With two exceptions the number of references at the end of each chapter has a maximum of ten. This restraint is commendable in a book of this nature, but occasionally results in a misleading impression. For instance, the short section dealing with the hydrostatic pressure of gradients contains only recent references and bears no hint that the existence of pressure gradients in any solution being centrifuged has long been recognised.

As there is a paucity of publications covering the same field at an elementary level, this book should find wide acceptance, especially as the price of the paperback should encourage younger workers to have a personal copy.

Circle No. 18 on Reader Enquiry Card

Modification of perceptual systems

Perceptual Modification: Adapting to Altered Sensory Environments. By R. B. Welch. (Academic: New York, San Francisco and London, 1978.) $24.50; £15.90.

THIS excellent book provides the most comprehensive review currently available of research on adaptation of the human senses to rearrangement of the stimulus field. The author has carefully summarised the principal findings of over 500 relevant experiments both published and unpublished, beginning with the late nineteenth century, and including important works completed only during the present year. The research methods used in each experiment are described clearly and succinctly, and are assessed with an objective attitude that is pleasantly refreshing in a field in which evaluative reviews can often be exceedingly biased.

The greater proportion of this book is devoted to examining the diverse types of adaptation to prismatic-induced distortions of the visual field. The various mechanisms that have been proposed to account for the adaptive characteristics of the visual system are presented in detail, and their relative success in explaining the different types of adaptation to visual distortions is reviewed critically. In comparing these mechanisms, the author is careful to make an important distinction between adaptive changes occurring specifically within the visual system and adaptive changes in how vision and movement are coordinated. The failure to make that distinction has often been a source of conflicting results in previous research studies.

The outstanding sections of this book are the reviews on the necessary and sufficient conditions for adaptation to prismatic displacement, adaptation to visual transposition, adaptation to contour distortions, and differences in adaptibility among species and individuals. I was particularly impressed by the logical transition from the review of research on adaptation to inversions of the visual field to the review of research on adaptation to small angular rotations of the visual field. His treatment of these topics was notably insightful and informative; a consequence of an exceptionally clear presentation.

The superior chapter in this book, however, is that on curvature adaptation, in which the author effectively contrasts adaptive changes in visual mechanisms used for processing information about objective shape with those used for processing information about object location. The classical controversy over the role of 'active' as against 'passive' movement in leading to each type of adaptation is also treated most elegantly in that chapter.

If the book has a weakness, it would be the author's commitment to try to make sense out of each and every one of the many diverse findings that he so thoroughly summarises. As he himself points out, there seems to be an almost unlimited number of factors that can contribute to perceptual adaptation. In the final chapter, he proposes a simple theoretical model with the intention being to provide a complete account of perceptual adaptation and thereby resolve numerous controversies in the literature. Although his model does serve well as a descriptive summary of the types of conditions that lead to perceptual adaptation, it really does not provide new insights into what the fundamental underlying processes might be. My suspicion is that there are many such processes, making an adequate model necessarily more complex than the author acknowledges.

This, however, is a minor criticism; in general, the book is an excellent summary of our current state of knowledge about the extent to which perceptual systems can be modified. It is highly recommended not only as a valuable reference for the professional researcher, but also as an informative introduction for the novice. I think the single most impressive feature of the book is the author's skill at organising an overwhelming number of isolated experiments, so as to provide the reader with a coherent account of one of the most confusing areas of visual perception.

Catecholamine receptors

Receptor Binding Studies in Adrenergic Pharmacology. By L. T. Williams and R. J. Lefkowitz. Pp. 157. (Raven: New York, $21.45.

THE proposal by Ahlquist thirty years ago that the responses of tissues to catecholamines are mediated by either α- or β-adrenoceptors has formed the basis of the development of a great number of agonist and antagonist drugs for these receptor sites. It has been somewhat surprising therefore, that despite this rich selection of pharmacological probes, reliable techniques to directly identify catecholamine receptors have only been developed over the past three to four years. However, over this latter period a multitude of research papers have been published describing direct labelling techniques, and substantial advances have been made in our understanding of the characteristics and regulation of these important recognition sites.

The authors of this monograph have played major roles in the development of radiolabelled ligand binding techniques for both α- and β-adrenoceptors. It is therefore to be expected that much of this book describes, in considerable depth, work from their own laboratories. The authors have, however, written useful introductory and linking chapters. There are succinct accounts of the pharmacology of adrenergic receptors, theory of ligand–receptor interactions and a historical perspective reviewing some of the frustrations and disappointments that were inherent in the development of these techniques. The chapter on methodological approaches contains a few 'tricks of the trade' that may be useful for those embarking on these techniques. However, it was somewhat disappointing that discussion of atypical binding characteristics such as those associated with negative co-operativity and multiple receptor sites, are dealt with only superficially. Nevertheless, the subsequent chapters, devoted to the pharmacological characteristics of α- and β-adrenoceptor binding sites, are particularly detailed and emphasis is rightly placed on the importance of using radiolabelled agonists as well as antagonists.

The development of adrenergic receptor binding techniques has undoubtedly given us a new insight into the way cells may regulate their responsiveness to catecholamines. A chapter devoted entirely to this topic includes a useful account of the theoretical consequences of 'spare receptors' and the intracellular amplification of extracellular signals. Homologous and heterologous hormonal regulation of adrenergic responsiveness are discussed in some depth, though other aspects such as receptor modulation in developing tissue and genetic influences receive less attention.

Although there is no sign that the initial explosive increase in adrenergic receptor research is saturating, this book nevertheless is a timely review and the lucid style of the authors should ensure that it will become a primary and valuable source of information in adrenergic receptor pharmacology.

EXPERIMENTAL LUNG RESEARCH

a new journal from Elsevier North Holland, Inc.

Editor-in-Chief
Paul Nettesheim, Chief of Laboratory, Pulmonary Function and Toxicology, National Institute of Environmental Health Sciences, Research Triangle Park, North Carolina, U.S.A.

Aims and Scope
The journal will publish original studies in the major fields of experimental lung research. Emphasis will be placed on investigations concerned with mechanisms of pulmonary biology and pathobiology conducted at the biochemical, subcellular, cellular, and tissue level. The journal will also publish reports of important advances. Occasionally, qualified individuals will be invited to review research topics of special importance or timeliness.

Subscription Information
EXPERIMENTAL LUNG RESEARCH will begin publication in mid-1979. Volume 1 will consist of four issues. Subscription Rates: $30.00 Individual $60.00 Institutional. Subscribers outside the U.S.A. should add $4.00 for surface mail, $10.00 for air delivery to Europe and Canada, and $16.00 for air delivery to the rest of the world.

Write now to reserve your sample copy.

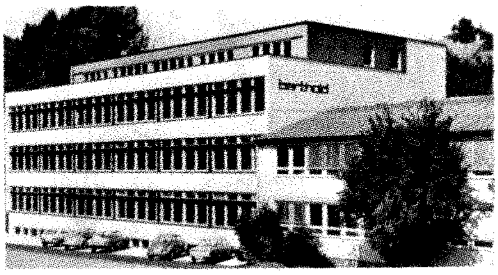
berthold INFORMATION

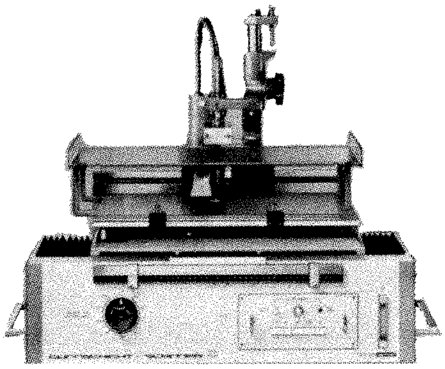
May we introduce ourselves? The name in Berthold



Chances are that you may never have heard of a company with the typically German-sounding name of Laboratorium Prof. Dr. Berthold. The probability, however, is steeply rising that you will encounter one or the other piece of Berthold instruments in any Life Sciences or Medicine Lab handling radioactive isotopes.

Berthold, whose factory is situated at Wildbad (Black Forest) F.R.G., is a fast growing enterprise designing and manufacturing Radiation Measuring Systems for Industry, Science, and Medicine since more than 25 years. Today the company owns branch offices in Belgium, France, Switzerland and Austria and has representatives in nearly30 countries all over the world — the youngest one being Laboratory Impex Ltd. of Twickenham, Great Britain.

It all began with scanners for the thin-layer and paper chromatography. The thin-layer scanner succeeded rapidly in becoming widely known and valued throughout the world. Today there are well over 1000 thin-layer scanners in operation!

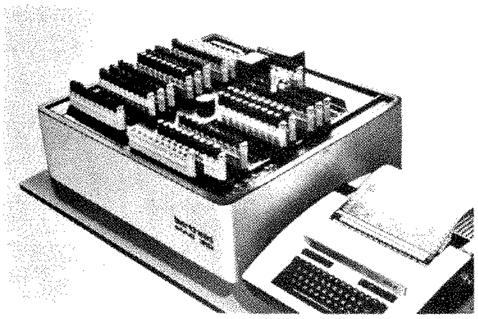


Thin Layer Scanner LB 2723

Circle No. 08 on Reader Enquiry Card.

Other novel and in most cases patented, instrumentation followed: first for radiogas-chromatography, then for column radiochromatography, to be finally followed by the Beta Camera for thin-layer chromatograms.

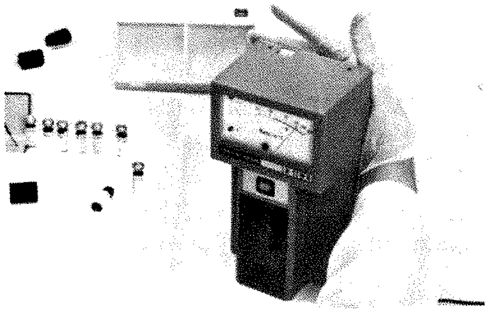
An important step was our entry into the field of liquid scintillation measurement. We realized that we would not be welcome in an already fiercely contested market. But our intense efforts to create a modern concept in equipment engineering and data processing, of high quality and, last but not least, with a favourable price-efficiency ratio, contributed to a genuine breakthrough. So today we are one of the leading companies with a well established reputation in the field of liquid scintillation spectrometers.



Gamma — Sample Changer LB 310

Circle No. 19 on Reader Enquiry Card.

The introduction of the new automatic gamma sample changer was somewhat easier. This was probably a matter of having had the right apparatus at the right time to take advantage of the radioimmuno assay boom. Still, our immediate success came as a surprise — even to us.



Portable Contamination Monitor
LB 1210B

Circle No. 20 on Reader Enquiry Card.

And there is yet another speciality of Berthold, the radiation protection instruments. A complete line of monitors of most advanced design is offered. As an example only, it may be mentioned that Berthold one year ago introduced the sealed-off, Xenon-filled propertional counter tubes with 100cm^2, 200 cm^2 or 900 cm^2 effective window area which revolutionized completely contamination measuring customs in Nuclear Medicine. If you are interested to get to know further this dynamic company and its products, please contact

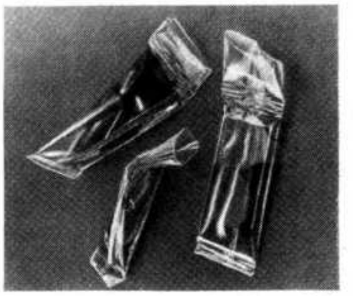
what's new—radioactivity measurement

These notes, prepared from material provided by the manufacturers, are intended to give an outline of the range of products on the market. More detailed information may be obtained by circling the appropriate numbers on the Reader Enquiry Card, bound inside the cover.
A feature on laboratory design and safety will appear in the 15 February issue.

Nalge (Sybron). Nalge offers a new system for scintillation counting based on a new principle: the Filmware tube. Filmware scintillation tubes combine the advantages and eliminate the disadvantages of glass and plastic vials. This system costs $60 to $250 less per 1,000 samples than conventional systems. Filmware tubes are available in two sizes—3 ml and 10 ml. In the Filmware tube, 1 ml of cocktail is distributed vertically for the length of the photomultiplier tube, which therefore gets a good, efficient look at it. In addition, it is possible with the 20 ml vial for the liquid level to go above the height of the photomultiplier tube. The Filmware tube gives optimal exposure to the photomultiplier tube, and often results in greater efficiency than standard vials. Like glass, Filmware tubes allow little if any loss of toluene.

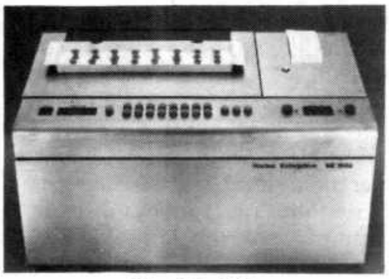


Filmware scintillation tubes from Nalge

A major criticism of glass vials is that certain liquids, proteins, and ions can adsorb on to the walls. With Filmware tubes, there is no wall adsorption.
Circle No. 27 on Reader Enquiry Card.

Packard. A new two-dimensional radioactivity scanner for chromatographic plates and film has been introduced by Packard. The Model 7230 scanner will detect the activity of all β-emitting radionuclides and many low energy, γ-emitting radionuclides on thin-layer plates and film. Chromatograms up to 20 cm × 20 cm are placed on a tray which is inserted into the instrument, and a Geiger detector is arranged to scan the chromatograms in both the x and y directions. A stylus mounted above the detector provides a 'dot' impression on sensitised paper as the detector senses the radioactivity and an exact copy of the distribution of activity is produced as a 'dot' pattern. Many scanning speeds can be selected and collimators to restrict the detection area provide accurate resolution between closely separated regions of activity.
Circle No. 28 on Reader Enquiry Card.

Nuclear Enterprises. NE 1600 from Nuclear Enterprises is a new concept in iodine-125 and cobalt-57 sample counting. By simultaneous counting through-put almost 20 times greater than that of orthodox instruments is achieved.
Circle No. 29 on Reader Enquiry Card.



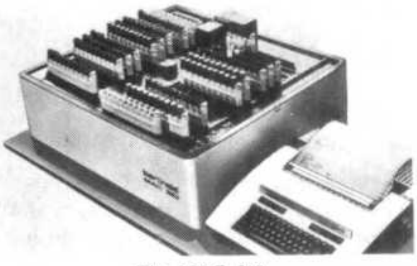
The NE 1600

LKB. The LKB 2258 PMV Cryomicrotome cuts sections of hard materials such as bone or teeth as well as soft tissues or whole animals. It is a compact heavy duty design for stable operation at low temperatures.
Circle No. 26 on Reader Enquiry Card.

Research Products International Corporation produce the G-M tube environmental monitor, Model 6-70. Supplied with a special compensated MC-70 type G-M tube, this instrument is designed for determining environmental γ radiation levels. The highly sensitive detector is suitable for measuring low intensity radiation within a reasonable time period. Sensitivity is approximately 150 pulses s^{-1} for a $1\,\mu R\,h^{-1}$ exposure rate. Bio-Count is a new cocktail from RPI for counting aqueous samples in a beta counter. It allows the incorporation of up to 3.5 ml of aqueous sample in 10 ml of cocktail without forming a gel. The phase separation region of BioCount, 1.5–1.8 ml, is extremely narrow and in the range that normally does not interfere with most counting applications.
Circle No. 30 on Reader Enquiry Card.

Amersham Corporation. Several new products and services of interest to users of nuclear instrumentation are available from Amersham. A sample preparation advisory service for liquid scintillation counting is now provided. Should users wish to discuss sample preparation problems, they should call (800)-323 9750 and ask for Technical Services Department. An applications laboratory will perform trials and make recommendations on difficult samples. Amersham has also added a number of new radioactivity standards to their extensive range. The new products include standardised solutions of carbon-14 (as glucose), cerium-139, cobalt-56, gallium-67, indium-111, iridium-192, krypton-85, mercury-197, molybdenum-99, tin-113 and xenon-133. Amersham has an extensive line available of liquid scintillation standards and quenched sets from stock. Custom designed quenched standards sets are also prepared to meet customers' needs.
Circle No. 31 on Reader Enquiry Card.

Berthold. The Berthold MAG 310 gamma counter is available in two basic versions, the simplest providing output of data in c.p.m. (and for RIA, with nonspecific binding subtraction) and the MAG 310 R, with full multi-user RIA processing on-line. The MAG 310 is a bench mounted microprocessor based instrument, with rack loading for up to 310 samples. Each rack is positively identified numerically and per user. Thus racks out of sequence can be adequately dealt with by the computer software, illuminating a source of weakness in some other systems. In its standard form sufficient shielding is supplied to allow a full range of isotopes to be counted up to and including iron-59. Selection of iodine-125 or another isotope is made automatically via the multi-user system. For laboratories where several operators are to make use of a single system, it is convenient that conversation with the microprocessor (via the output device) is conducted in English.
Circle No. 32 on Reader Enquiry Card.

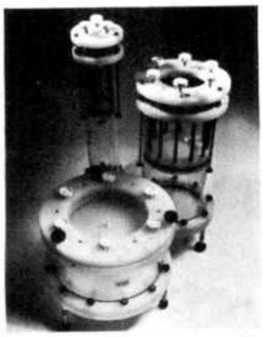


The MAG 310

newly on the market

Liquid nitrogen cryostat. Oxford Instruments. Test trials carried out by Oxford Instruments have shown that their DN700M liquid nitrogen Mossbauer cryostat is capable of operating within a variable temperature range of 77–300 K, with a stability of ± 0.1K. Moreover, it will maintain this degree of stability at 77 K for more than five days. The standard version of the DN700M has a top-loading sample space of 20 mm clear diameter, and a sample change time of only 30 s. The equipment, which incorporates a platinum sensor and a 39 Ω heater, takes only 20 min to cool down and warm up. The tail has a diameter of 63.5 mm with two in-line, wrap-round aluminised mylar windows, giving 25 mm clear access. Nitrogen flow to the heat exchanger is simply controlled using a valve in the gas exhaust line. An activated charcoal sorb is used to maintain a good vacuum.
Circle No. 33 on Reader Enquiry Card.

Chromatography columns. Wright. A new range of production chromatography columns has been launched by Wright Scientific. Their special features include 'snap-on' sinters and 'pressurised' filling facilities. This large range allows you to choose your exact requirements without buying more than you need.
Circle No. 34 on Reader Enquiry Card.



Wright chromatography columns

Light chopper. Rofin. Rofin has developed a variable aperture, variable frequency light chopper which has a chopping blade whose aperture is variable from a very narrow slit to 90°, making the mark-space ratio of the chopped signal continuously variable. Features include chopping frequency variable over 3–200 Hz, high stability of frequency, F/2 input aperture cone, sync output and output control for internal or external frequency drive, 360° phase control and digital LED display housing.
Circle No. 35 on Reader Enquiry Card.

Integrating sphere calibration source. Glen Creston. The model 420 calibration source is now available from Glen Creston. It consists of an 8 in diameter integrating sphere and a 45 W tungsten–halogen lamp. The lamp is mounted on a movable platform, and an aperture wheel containing five different apertures is mounted in front of the integrating sphere. By altering the lamp position and changing the apertures one can continuously vary the output from the source. The standard source is calibrated for both illuminance and spectral irradiance over the range of 350–1,200 nm. Calibrations for the range 250–350 nm and 1,200–2,500 nm are also available.
Circle No. 36 on Reader Enquiry Card.

Automatic serum dispenser. Dynatech. An automatic serum dispensing unit, the 'seromat', is now available from Dynatech, and allows up to 60 0.001 or 0.002 ml volumes of typing sera to be dispensed into the corresponding wells of a pre-oiled Teresaki tissue-typing plate. Push-button simplicity of operation means that the complete cycle time for loading a plate, dispensing the serum into the wells and unloading the plate is less than 5s. The seromat dispensing head consists of 60 micropipettes grouped to match the format of a Teresaki plate. Each micropipette has its own 200-μl reservoir and, once the pipettes are primed with a panel of typing sera, up to 200 plates can be seeded in under 30 min.
Circle No. 37 on Reader Enquiry Card.

Illuminated pocket microscope. Intel Electronic Components announce the availability of a miniature lightweight illuminated microscope which contains a comprehensive graticule enabling the area under inspection to be measured. Calibrations on the graticule are up to 4 mm in increments of 0.1 mm and angles from 30° to 90° are marked, together with a circular measurement of 0.2, 0.3, 0.4, and 0.5 mm. This pocket microscope is only 125 mm long, and has a wide field of view at × 20 magnification. It incorporates a unique built in illumination and easy focusing system. Illumination is powered by standard batteries, 1.5 V, and a screw base 2.3 V 0.2 A bulb.
Circle No. 38 on Reader Enquiry Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the cover.

Microcellcounter. TOA. A new microcellcounter offering computer capability and an optional data printer has been introduced by TOA Medical Electronics. The Sysmex CC-120 is the nucleus of a modular hematology system. The options which complete the system include: the Sysmex auto diluter AD-220, which aspirates, dilutes and ejects the sample, the ND-900 which displays the sample being analysed, and the DP-411 data printer, which prints a three-digit sample number, three-digit measurement results and three kinds of data. The mercury-free manometer, < 9 s counting time, counting time display, audible aperture clog alarm and reverse aperture flushing are standard features of the CC-120 microcellcounter.
Circle No. 39 on Reader Enquiry Card.

The Sysmex CC-120

High performance cooling thermostats. KLS. A new range of high performance cooling thermostats have been added to the Julabo equipment available from Kent Laboratory Services, designed for use in research, clinical chemistry and industrial laboratories. The main features of the latest range include proportional temperature control, a virtually noiseless compressor operation, and an automatic on–off switching of compressor to eliminate operating errors. A high capacity circulation pump is built in with a double air ventilation system, and an excess temperature and liquid level protection device is included for unattended day and night operation.
Circle No. 40 on Reader Enquiry Card.

HPLC column. Whatman. The Whatman Partisil-5 ODS high pressure liquid chromatography column provides a guaranteed minimum of 11,000 plates per column. The column is 25 cm long (4.6 mm diameter) giving a minimum of 45,000 plates per m. This new column is fully silanised, with no remaining adsorption sites, and provides pure C18 reversed-phase chromatography.
Circle No. 41 on Reader Enquiry Card.

THE NEW BREED

Simplifies large area distribution studies

We have not come as far as the zipper, yet.... but with the LKB 2250 PMV Cryo-Microtome we are getting close. When combined with whole-body autoradiography this Cryo-Microtome makes it easier than ever to investigate the fate of drugs, chemicals and other biochemically interesting compounds.

With this Cryo-Microtome you can collect sections ideal for both whole-body autoradiography and tissue sampling. Every section is of the same high quality essential for quantitative distribution studies. The LKB 2250 PMV Cryo-Microtome sections animals up to 150×450 mm easily as well as hard materials such as non-decalcified bone and teeth.

Automatic specimen-trimming plus a unique automatic cleaning system provides safety and efficiency. The extremely high temperature-stability enables you to cut section after section without interruptions. Afterwards the sections can be completely freeze-dried right in the cryostat.

Many conscientious companies already use the LKB 2250 PMV Cryo-Microtome to test their products for possible unexpected results before putting them on the market. Wouldn't you like to have this extra insurance for your products too?

For further information send for the new full-colour brochure.

Appointment of

Director Dental Unit

(Readvertisement)

The Medical Research Council invites applications for the post of DIRECTOR of a new Dental Unit. The first choice for the location of the new unit is Bristol, but other locations are not excluded.

The research programme of the unit will be a matter for discussion between the new Director and the Council, having regard to the particular interests of the candidate selected.

Candidates should be persons of high scientific standing – preferably, but not necessarily, with a dental qualification – and proven ability in leading a research team.

The salary will be within the range for the Council's Special Appointments Grade, which is equivalent to the Universities' professorial range.

Further particulars, including details of the method of application, may be obtained from Miss N S Jones, 20 Park Crescent, London W1N 4AL.

This post is open to both male and female applicants.

The final date for the receipt of applications is 31 March, 1979.

MRC
Medical Research Council

GRADUATE
or
POSTGRADUATE

in biochemistry, pharmacology, or medicine required for research project on the use of liposome-sequestered cytotoxic agents in experimental chronic inflammatory arthritis. Apply in writing, giving full curriculum vitae to the Administrative Secretary, Strangeways Research Laboratory, Wort's Causeway, Cambridge CB1 4RN. 9189(A)

THE UNIVERSITY OF SUSSEX
SCHOOL OF BIOLOGICAL SCIENCES
RESEARCH OFFICERSHIP

Graduate required to work on a three-year S.R.C. financed research project investigating hormonal effects on the stability of memory traces and of attention. The project is due to commence April 1, 1979, though students graduating in Summer 1979 will be considered.

Starting salary in the range £3,384 to £3,883 p.a. (under review), with superannuation benefits.

Applications as soon as possible to Professor R. J. Andrew, School of Biological Sciences, University of Sussex, Falmer, Brighton BN1 9QG, from whom further details are available. 9242(A)

PLANT BREEDING INSTITUTE

Maris Lane, Trumpington,
Cambridge CB2 2LQ

HIGHER SCIENTIFIC OFFICER/ SENIOR SCIENTIFIC OFFICER
CYTOGENETICS DEPARTMENT

A Research Worker with experience in plant genetics and cytology is required who is prepared to develop the new techniques of DNA probe analysis in order to promote the understanding of the consequences of particular types of DNA organisation on genetic activities in plants, particularly wheat.

Candidates should have a 1st or Upper 2nd Class Honours Degree in an appropriate biological science and at least two years' postgraduate experience in plant cytogenetics or related research.

The appointment will be as Higher Scientific Officer (£4,101 to £5,448 per annum) or Senior Scientific Officer (£5,154 to £6,898 per annum). At least four years relevant postgraduate experience is required for appointment as Senior Scientific Officer.

Applications with curriculum vitae and the names and addresses of three referees should be sent to the Assistant Secretary (Establishment) by February 12, 1979.

Please quote reference CYT/39.
9195(A)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF BOTANY

Applications are invited for the post of Demonstrator or Senior Demonstrator to assist in teaching and research in bacterial taxonomy. Preference will be given to applicants with experience in numerical methods of classification and identification. The duties of the post will commence on April 1, 1979, or as soon as convenient thereafter; for one year in the first instance, and may be renewed, but not normally more than twice.

The initial salary will be within the range £3,384 to £4,882 per annum.

Applications, together with the names of three referees should be received not later than February 9, 1979, by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote ref. RV/451/N. 9218(A)

PALEOSERVICES LIMITED OF WATFORD

require a

with Mesozoic and/or Paleozoic experience to undertake studies of Well sequences and basin analyses.

Salary negotiable.

Please apply in writing to: Paleoservices Limited, Unit 2, Polychrome Building, Sandown Road, Watford, Herts WD2 4UB. 9093(A)

MEDICAL RESEARCH COUNCIL
PNEUMOCONIOSIS UNIT
LLANDOUGH HOSPITAL

PENARTH,
SOUTH GLAMORGAN
CF6 1XW

Applications are invited for a consultant grade post in RESPIRATORY MEDICINE to carry out research into the cause, diagnosis, prevention and treatment of non-infectious extrinsic lung disease. The work includes the direction of a well staffed and equipped respiratory function research laboratory as well as the care of in and out patients at Llandough Hospital.

The successful applicant will be expected to pursue his or her own research as well as collaborate in projects involving other sections of the unit.

Applicants should be qualified to hold a consultant post in respiratory medicine and have special experience in the laboratory investigation of respiratory function. The successful applicant will be offered an unlimited appointment to the Council's clinical staff. Terms of employment will be those normal for M.R.C. Clinical staff with honorary consultant sessions in the National Health Service: Salary £9,528 to £12,084 and compulsory pension scheme.

Applicants should contact the Director, M.R.C. Pneumoconiosis Unit, from whom further information and an application form may be obtained. Closing date—February 24, 1979. 9162(A)

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING
CHEMIST/PHYSICIST
(Nutrition Department)

A scientist with considerable technical ability is required to run and maintain an Isotope Mass Spectrometer and an Automatic Optical Emission Spectrometer used in the analysis of ^{15}N. The person appointed will be a member of a small team engaged in studies of nitrogen metabolism in animals.

Applicants should have a degree, H.N.C. or the equivalent in Physics or Chemistry and an interest in biomedical research; or similar qualification in Biochemistry with experience in mass spectrometry. Some knowledge of electronics is desirable.

Appointment will be as Scientific Officer (£2,839 to £4,415) or Higher Scientific Officer (£4,101 to £5,448) according to experience. At least five years' relevant postgraduate research or other approved experience is required for appointment as Higher Scientific Officer.

Application forms are obtainable from the Secretary, N.I.R.D., Shinfield, Reading RG2 9AT. Quote reference 78/36. 9193(A)

GUY'S HOSPITAL MEDICAL SCHOOL
LABORATORY SCIENTIFIC OFFICER

required until September 30, 1980 t work in the Department of Chemica Pathology. Duties will include the *i vitro* cultivation of malaria parasites Previous experience in tissue cultur techniques essential. Salary for qualified Laboratory Scientific Officer no less than £3,261 plus £354 Londo Weighting.

Apply in writing, stating age an giving details of qualifications an experience, to the Secretary, Guy' Hospital Medical School, London Bridge SE1 9RT, quoting Ref. C.H.1.
9228(A)

UNIVERSITY OF GLASGOW
DEPARTMENT OF BIOCHEMISTRY
POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a Postdoctoral Research Assistant to work with Dr J. P. Goddard in his Scienc Research Council grant-aided projec on structure-function relationships i transfer RNA. The current researc is on the recognition of tRNA^{Ty} and tyrtRNA synthetase from B stearothermophilus.

The position is for one year an salary will be within range 1A of th salary scales for Research and Analogous Staff, £3,883 to £4,382, accordin to qualifications, age and experience Appropriate Superannuation Schem will apply.

Applications enclosing a curriculu vitae and the names of two referee should be submitted by February 9 1979, to Dr J. P. Goddard, Department of Biochemistry, University o Glasgow, Glasgow G12 8QQ.

In reply please quote Ref. No 4346M. 9215(A)

NEUROBIOLOGY AND BEHAVIOUR

A position at the Assistant Professor level is available in the Biology Department, Princeton University. Faculty in the Neurobiology and Behaviour area include M. Constantine-Paton, H. Horn, A. Gelperin, J. Gould, R. Lisk and W. Quinn Evidence of exceptional promise in research is essential Applicants should send curriculum vitae, statement of research experience and three letters of recommendation to Dr Alan Gelperin, Neurobiology Search Committee, Department of Biology, Princeton University, Princeton, N J 08540 Princeton University is an Equal Opportunity/Affirmative Action Employer. 9112(A)

UNIVERSITY OF LEICESTER
DEPARTMENT OF GENETICS
POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited from persons with an interest in biochemistry or molecular genetics for a postdoctoral research position financed by an M R C. Project Grant. The project will investigate the mechanism of synthesis and assembly into membranes of specific cytoplasmic and outer membrane polypeptides in *E. coli*. This will involve the use of cloned genes for membrane proteins and coupled transcription/translation from DNA templates in *in vitro* systems. The work is likely to involve close collaboration with research groups in the Department studying the physiology of cell division in *E coli* and the cloning of division proteins. The appointment will be tenable for up to 3 years from February 1, 1979 or as soon after as can be arranged

Starting salary £3,660 per annum with full superannuation provision

Applications with names of two referees to Dr I. B Holland, Department of Genetics, University of Leicester, Leicester LE1 7RH

9130(A)

ST. MARY'S HOSPITAL MEDICAL SCHOOL
(University of London)
Paddington, London W2 1PG
GRADUATE IN PHYSIOLOGY OR PHARMACOLOGY

who will be expected to register for a higher degree, required to join team investigating the mechanism of action to drugs affecting gastric secretion

Appointment, which can be taken up immediately, is for one year initially with prospect of extension for further two years. Project jointly organised between Departments of Physiology and Academic Surgical Unit.

Further information from Mr S Knight (Tel: (01)-723 1252, ext. 133, to whom application with curriculum vitae may be sent at above address

9126(A)

UNIVERSITY OF EDINBURGH
DEPARTMENT OF BACTERIOLOGY
POSTDOCTORAL FELLOW/ RESEARCH ASSOCIATE

required to work on a Cancer Research Campaign sponsored project in tumour immunology. Experience in working with tumours or in the field of cellular immunology would be desirable. Salary on National Range IA.

Send c.v to Dr W. H. McBride, Department of Bacteriology, Edinburgh University Medical School, Teviot Place, Edinburgh EH8 9AG, Scotland. Please quote Reference 5058.

9090(A)

BRUNEL UNIVERSITY
DEPARTMENT OF APPLIED BIOLOGY

Applications are invited for the post of postdoctoral Research Fellow (for a period of three years) for work on cultured cystic fibrosis cells. The work will be performed in collaboration with Dr Roger Dean, Reader-elect in Applied Biology. The project is being funded by The Cystic Fibrosis Trust Dr Dean's particular interests are in lysosomes, mechanisms of protein degradation, macrophage activation and secretory processes.

The post is particularly suitable for a cell biologist, or a biochemist with experience with cultured cells

Salary within the range £3,910 to £5,367 (under review), plus £450 per annum London Allowance.

Write for application form and further particulars to the Assistant Secretary (Establishment), Brunel University, Uxbridge, Middlesex UB8 3PH, or telephone Uxbridge 37188, extension 49. Closing date February 9, 1979. 9219(A)

UNIVERSITY OF LONDON
Institute of Neurology
DEPARTMENT OF NEUROCHEMISTRY

Applications are invited for two postdoctoral posts Grade 1A in a team working on the metabolism and role of 5-hydroxytryptamine (and related topics) and supported by a recently renewed 5-year M R.C programme grant. Experience in at least one of the following fields essential neurochemistry, neuropharmacology, behaviour Initial salary £4,333 to £6,054 (including London allowance), depending on experience.

Applications with c.v. and names of two referees to Professor G Curzon, Department of Neurochemistry, 33 John's Mews, London WC1, by February 23, 1979

9220(A)

TECHNICIAN/ RESEARCH OFFICER

required to work with Professor Mitchison at Tumour Immunology Unit on viral immunology Work will involve virus preparation and titration, animal work such as immunisations and bleeding, and other immunological techniques Candidates should have an H N C./Degree and at least two years laboratory experience. An interest in immunology and experience in virology and tissue culture would be valuable Salary range £3,261 to £4,902 plus London Weighting

For application form and further information please write or telephone Mrs Nelson, Imperial Cancer Research Fund, Lincoln's Inn Fields, London W C 2. Telephone 01-242 0200. Ext 305 Quoting ref. 77/79 9191(A)

UNIVERSITY OF READING
NATIONAL COLLEGE OF FOOD TECHNOLOGY
Short-term Lectureship in Applied Biochemistry

Applications are invited for the above post tenable at the National College of Food Technology, Weybridge, Surrey, for the duration of the Summer Term (mid-April—beginning July, 1979) The duties are to give a short course of lectures on food biochemistry and to supervise related practical classes Payment for the Term will be within the range £1,200 to £1,600.

Applications with a curriculum vitae should reach the Principal, National College of Food Technology, St George's Avenue, Weybridge, Surrey by January 31, 1979. 9192(A)

CSIRO AUSTRALIA

Aircraft Operations Manager

Division of Cloud Physics
Sydney, NSW

CSIRO has a broad charter for research into primary and secondary industry areas The Organization has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

General: The Divisions' research activities are associated with the natural mechanisms of cloud and rain formation, artificial induction of rainfall by techniques such as cloud-seeding, and studies of atmospheric particles

Duties: Responsible for the co-ordination and performance of activities associated with the Division's use of aircraft

Advise research staff concerning the installation of scientific equipment in aircraft, undertake the layout design of such installations to meet research requirements and Department of Transport standards and liaise with installation contractors.

The appointee may be required to provide advice about aircraft available for charter and their suitability for research purposes, to negotiate with charter companies and to be generally responsible for the modification and use of chartered aircraft. The appointee will also be required to act as "Field Manager" during the course of a major cloud seeding experiment to be concucted over a five year period in Western Victoria As Field Manager the appointee will be responsible for all aspects of aircraft operations associated with the experiment, which involves the use of three aircraft. It will therefore be necessary for the appointee to be located at *Mildura* from August to mid November commencing in 1979 and over the same period for the ensuing four years.

Qualifications: An appropriate degree or diploma, or equivalent qualification Applicants should preferably have had considerable experience in the aircraft industry and be familiar with the operation, maintenance and modification of a wide variety of aircraft A good knowledge is required of D.O T airworthiness standards, especially those concerning structural modification and equipment installation.

Applicants should be physically fit to fly and prepared to participate in field operations involving absences from Sydney

Salary: Within the range $A17,115 to $A20,867 p.a Appropriate allowances are payable for extended duty away from Sydney.

Tenure: Indefinite with superannuation.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 425/59 should reach

The Personnel Officer, Australian Scientific Liaison Office,
Canberra House, 10-16 Maltravers Street, London WC2R 3EH,
by 16th FEBRUARY 1979.

Applications in U.S A and Canada should be sent to:
The Counsellor Scientific, Embassy of Australia,
1601 Massachusetts Avenue, N.W , Washington, D.C.,
20036, U.S.A. 9208(A)

AN FORAS TALUNTAIS
LAND RECLAMATION RESEARCH

Applications are invited for a post in an expanding land reclamation research programme, with particular emphasis on drainage The post will be in the Western Research Centre, at Creagh Station, Ballinrobe, Co. Mayo

ESSENTIAL: Honours University Degree, or equivalent, in Engineering, Agricultural Engineering or Agricultural Science

DESIRABLE: Postgraduate study and/or experience in soil/water relationships as affecting land reclamation and use.

Appointment up to and including Senior Research Officer level (salary maximum £8,465) depending on qualifications and experience Marriage and Childrens' allowances. Non-contributory Pension Scheme and provision for Widows' and Orphans'.

Application form and further particulars from Personnel Department, An Foras Taluntais, Headquarters, 19 Sandymount Avenue, Dublin 4. (Tel 688188). Latest date for receipt of completed forms Wednesday, January 24, 1979.

9158(A)

Biochemist

The Plant Protection Division of ICI wishes to recruit a biochemist with postgraduate research experience to play a part in the discovery of new insecticides An understanding of neurobiology would be desirable, but practical experience of insect biochemistry is not essential However, candidates must have considerable scientific flair and imagination, and the ability to draw on research in other fields

The successful applicant will join a multidisciplinary project team and will be responsible for the work of two graduate biochemists The job holder will be required to initiate research in areas of insect biochemistry that could lead to a synthetic programme or produce *in vitro* methods for detecting active chemicals Complementary work will be concerned with evaluating the mode of action of promising new insecticides and gaining an early understanding of the factors that may contribute to the development of resistance

We offer competitive salaries and there is a Company Profit Sharing Scheme Assistance with removal expenses and house purchase may also be available The Research Station is situated on a pleasant farm estate between Bracknell and Maidenhead in Berkshire .

If you are interested in this vacancy please write or telephone for an application form to

Mr D Spence, Personnel Officer, ICI Plant Protection Division, Jealott's Hill Research Station, Bracknell, Berkshire Telephone Bracknell 24701, ext 3350.

Please quote reference 79/Biochem

ICI

Plant Protection Division

9177(A)

AGRICULTURAL RESEARCH COUNCIL

FOOD RESEARCH INSTITUTE

Head of the

Microbiology Division

Senior Principal Scientific Officer

Applications are invited for this post from scientists with a broad experience in Microbiology.

Distinction in a relevant microbiological research area, preferably with a bacteriological background, is required and experience in food-related areas will be of special value. The total staff of the Division will be approximately 25 with at least five Principal Scientific Officers and appropriate support staff.

The Institute is housed in excellent laboratories in Norwich and takes a major role in the Council's research effort relating to food in the U.K.

The salary range for this appointment is £10,300 × 2 to £11,300 and there is a non-contributory superannuation scheme.

Further particulars and application forms are available from the **Secretary, ARC Food Research Institute, Colney Lane, Norwich, NR4 7UA, quoting Ref: 77/10. Closing date February 5, 1979.** 9197(A)

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

(University of Reading)

UTILISATION OF SKIMMED MILK

The following temporary research staff are required to work on a project supported by the E E C and concerned with improved utilisation of skimmed milk:

Two protein chemists/enzymologists,

A food technologist or chemical engineer;

A protein chemist, physical chemist or bio-physicist

Applicants should possess a 1st or upper 2nd class Honours Degree and have had at least four years' post-graduate research or other relevant experience Salaries will correspond to those of the Scientific Civil Service

Application forms are available from the Secretary, N I R D, Shinfield, Reading RG2 9AT Please quote reference 78/45 9194(A)

University of Cambridge LECTURESHIP Applications are invited for a University Lecturer in Botany to take up appointment from October 1, 1979 or as soon as possible thereafter The person appointed will be expected to provide teaching in the field of whole plant physiology and/or ecological plant physiology and to have research interests in the same areas of plant physiology The appointment will be for three years in the first instance, with the possibility of reappointment to the retiring age The salary is on an incremental scale rising from £5,367 to £8,257 per annum Applications with the names of two referees should be sent by March 31, 1979 to the Secretary of the Faculty Board of Biology 'A' Appointments Committee, Department of Applied Biology, Pembroke Street, Cambridge CB2 3DX, from whom further particulars may be obtained 9226(A)

UNIVERSITY OF ABERDEEN

DEPARTMENT OF ZOOLOGY

RESEARCH ASSISTANT

Applications are invited from graduates in zoology and those intending to graduate in 1979 to work with Dr D F Houlihan on "Energy cost and mechanisms of Transepithelial Transport in Insects"

Appointment will be from April 1, 1979, or as soon thereafter as possible, and will be for three years Commencing salary within Range 1B, £3,384 to £3,883 per annum, with appropriate placing

Further particulars from The Secretary, The University, Aberdeen, with whom applications (two copies) should be lodged by February 9, 1979, quoting Reference DH2 9163(A)

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for the post of Technician to assist with research in insect biochemistry Minimum qualification for this post is an O N C, but applications will be welcomed from candidates holding H N C or graduates or a degree in Biochemistry or Zoology Some experience of insect physiology an advantage but not essential The post is tenable for 2½ years in the first instance with a possibility of renewal Salary within a range up to £2,835 per annum (under review) according to qualifications and experience

Application forms may be obtained from The Registrar, The University, P O Box 147, Liverpool L69 3BX Quote Ref RV/456/N

9217(A)

UNIVERSITY OF SURREY

CHEMISTRY DEPARTMENT

TECHNICIANS

TECHNICIAN GRADE 5

£3,186 to £3,720 (under review)

A Grade 5 laboratory technician i required to assist in the daily runnin of laboratories with special responsibility for the departmental radiochemical laboratories The routine and research procedures may include operation and maintenance of a variety o sophisticated instruments, assistin with undergraduate or postgraduat courses, radiosynthesis, and maintenance of safety standards

Qualifications sought, H N C., H N D /Advanced City & Guilds and 8 to 9 years' experience.

TECHNICIAN GRADE 4

£2,955 to £3,402 (under review)

A Grade 4 Technician is required to assist in the running of the undergraduate laboratories, with specia responsibility for the Physics laboratory within the Chemistry department The Physics laboratory is an integra part of the Physical Science degree course and therefore a background in physics is desirable in addition to chemistry.

Qualifications sought O N C, O N D /Ordinary City & Guilds/2 A Levels and 5 to 8 years' experience.

Application forms for both of these posts may be obtained from the Staff Officer, University of Surrey, Guildford, Surrey GU2 5XH, or telephone Guildford 71281, extension 452

Closing date for applications February 12, 1979 9205(A)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF PHYSICS

TWO LECTURESHIPS

Applications are invited for two lectureships in the Department of Physics. The successful candidates will be required to contribute fully to the teaching programme in the Department One of them will be expected to join the Nuclear Structure Research Group, the other to join one of the other research groups in the Department They will be expected to take up their appointments not later than October 1, 1979.

Salary will be on the scale £3,883 to £7,754 (under review) plus superannuation

Further particulars are available from the Assistant Registrar, Science and Engineering, University of Birmingham, P O Box 363, Birmingham B15 2TT, to whom applications (three copies), including full curriculum vitae and the names of three referees should be sent by Friday, February 2, 1979 Please quote ref. ND1. 9222(A)

MEDICAL RESEARCH COUNCIL

Clinical Oncology and Radiotherapeutics Unit

require

a biochemical pharmacologist to participate in a programme on the pharmacokinetics and the metabolism of drugs and radiation sensitisers in animals and man Experience of high performance liquid chromatography is essential

The successful candidate will conduct routine drug estimations and will take part in the Unit's on-going research programme

The appointment will be for five years with a possibility of eventual tenure to retiring age. Candidates must have at least an upper second class honours degree and six years' relevant postgraduate experience

Salary on scale starting from £5,367 per annum

Applications, with full c v and names of two referees, should be sent to Miss F M Taylor, M R C Clinical Oncology and Radiotherapeutics Unit, The Medical School, Hill Road, Cambridge CB2 2QH, to be received not later than February 12, 1979.

9225(A)

UNIVERSITY OF WALES

UNIVERSITY COLLEGE OF SWANSEA

Senior Research Assistant

Applications are invited for the vacancy of

Senior Research Assistant in the Department of Botany and Microbiology.

The post is financed by N.E.R.C., to support work, under the supervision of Professor P. J. Syrett, on the biochemistry and physiology of nitrogen assimilation by marine photoplankton. Applicants should have a Ph.D. degree and research experience in biochemistry.

The appointment, which will be for one year in the first instance, with the possibility of renewal for a further two years, will be on the scale up to £4,382 per annum, together with U.S.S./U.S.D.P.S. benefits.

Further particulars and application forms (two copies) may be obtained from the Personnel Officer, University College of Swansea, Singleton Park, Swansea SA2 8PP, to whom they should be returned by Friday, February 2, 1979. 9161(A)

AUSTRALIAN NATIONAL UNIVERSITY OFFICE FOR RESEARCH IN ACADEMIC METHODS

An academic position is vacant in the Office for Research in Academic Methods (Head Mr A. H. Miller). O.R.A.M. was established in 1975 to improve facilities for teaching and learning within the University, to collect data necessary for educational planning, and to make the findings of educational research available to teaching and administrative staff.

Applicants should have experience in university teaching and should be qualified to undertake research into one or more aspects of higher education as part of a small independent team. There may be opportunities for a small amount of teaching in the appointee's own discipline, as this will help maintain contact with students and will provide the chance to practise innovations in course design, teaching and assessment. The appointee may be asked from time to time to be Acting Head of the Office in the absence of the Head.

Appointment will be for three years in the first instance, with the possibility, following review of reappointment for a further fixed term or to age 65. A three year secondment from an existing tenured position could be negotiated.

This post was advertised earlier as Research Fellow or Senior Research Fellow. The terms have now been slightly varied and the title has not yet been resolved. The applications received for the post when it was last advertised will be considered, unless candidates indicate that they are no longer interested.

Commencing salary will be in accordance with qualifications within the ranges $A15,179 to $A19,940 per annum or $A20,365 to $A23,737 per annum. Current exchange rates $A1 58p $US1.14.

Reasonable appointment expenses are paid. Superannuation benefits are available for applicants who are eligible to contribute. Assistance with housing is provided for an appointee from outside Canberra.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should obtain the further particulars from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. The closing date for receipt of applications is *February 16, 1979*. 9154(A)

Scientists for Neutron Beam Research

Rutherford Laboratory

The Rutherford Laboratory is constructing a new neutron source, known as the Spallation Neutron Source (SNS) which will provide intense pulsed neutron beams for condensed matter research by scientists from universities and polytechnics.

This is a major project of world significance which is planned for initial operation by 1982.

Preparation for exploitation has begun and this will require the progressive recruitment of neutron scattering specialists during the next few years to contribute in various areas, notably the design of neutron scattering instruments for the SNS, supervision of their operation, and the planning of support facilities such as sample preparation laboratories. In the short term, development studies on pulsed source instrumentation will be made using the Harwell electron linac and pulsed sources elsewhere. In addition the successful applicants will be expected to participate in scientific research projects usually in collaboration with the user community, and using the facilities at Harwell and the Institut Laue-Langevin (ILL), Grenoble. It is the intention that some of those recruited will be invited to work for extended periods at ILL to broaden their experience and to contribute to the ILL programme. There are opportunities for suitably qualified scientists, including theorists and experimenters, both for permanent appointments and for secondment. Applications will be considered from those able to fill posts promptly as well as later during 1979.

In the case of secondment, the Rutherford Laboratory would welcome applications or enquiries from staff in universities or similar institutions who have considerable experience in neutron scattering and who would be interested in working at the Laboratory for periods of 2-5 years. The precise terms of secondment would be subject to negotiation between a successful candidate, his employer and the Laboratory.

Appointments to permanent posts in the Science Group will be made at SO/HSO levels. Applicants for these posts will preferably have a good honours/PhD degree plus relevant experience. Exceptionally an appointment might be made at a more senior level (SSO or PSO).

Salary scales: Scientific Officer £3,037 to £4,724.
Higher Scientific Officer £4,388 to £5,829.
Contact:- Jane Griffiths in the Personnel Group on Abingdon (0235) 21900 Ext. 510. Or write to her quoting reference VN 763.

Closing date for applications February 9th 1979.

CSIRO AUSTRALIA

Division of Fisheries and Oceanography
Sydney, NSW

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field: FISHERIES BIOLOGY

General: The Division is Australia's principal marine research institution with about 70 scientists investigating the physical, chemical and biological features including fisheries of the oceans around Australia. Headquarters of the Division are at Cronulla, Sydney, with regional laboratories in Perth, Brisbane and a field laboratory at Karumba. On-line access to a Cyber 76 computer is available. Two well-equipped medium sized chartered vessels are available for oceanographical research and there are several smaller CSIRO vessels.

1. Research Scientist

Reference Number 320/611

Duties: To take a leading role in the development and execution of a research programme on marine fish resources around Australia including the supervision and co-ordination of other researchers in this field. Initially attention will be directed to demersal and pelagic resources associated with the continental mass. Field investigations on the Division's vessel and on fishing vessels in the open sea will be required. Temporary posting to other parts of Australia might be necessary.

Qualifications: A biologist with considerable experience is being sought. Basic formal qualifications are Ph.D degree or equivalent qualifications in one of the ecological sciences or fisheries with training in mathematics and statistics, together with demonstrable research ability, and ability to work at sea.

Salary: Senior Research Scientist: $A18,819 to $A21,543 p.a. or Principal Research Scientist: $A22,353 to $A25,354 p.a.

Tenure: Indefinite with superannuation.

2. Postdoctoral Research Fellow

Reference Number 320/610

Duties: To participate in the development and execution of a research programme on marine fish resources around Australia. Initially attention will be directed to demersal and pelagic resources associated with the contental mass. Field investigations on the Division's vessels and on fishing vessels in the open sea will be involved. Temporary posting to other parts of Australia may be required.

Qualifications: A Ph.D degree or equivalent in one of the ecological sciences or fisheries with training in mathematics and statistics, together with demonstrable research ability, and ability to work at sea.

Salary: Research Scientist: $A14,829 to $A18,177 p.a. or Senior Research Scientist: $A18,819 to $A21,543 p.a.

Tenure: 3 to 5 year fixed term appointment with superannuation.

Applications IN DUPLICATE, stating FULL personal and professional details, the names and addresses of at least two professional referees, and QUOTING THE APPROPRIATE REFERENCE NUMBER(S) should reach:

The Personnel Officer, Australian Scientific Liaison Office,
Canberra House, Maltravers Street, London WC2R 3EH
by 16th FEBRUARY 1979

Applications in U.S.A. and Canada should be sent to:
The Counsellor (Scientific) Embassy of Australia,
1601 Massachusetts Avenue N.W., Washington, D.C. 20036

9212(A)

AHMADU BELLO UNIVERSITY, NIGERIA

Applications are invited for the posts of SENIOR LECTURERS and LECTURERS in the DEPARTMENT OF HUMAN ANATOMY. For the post of Senior Lecturers, candidates should possess a higher degree, have considerable teaching and some research experience preferably at university level. For the post of Lecturers, candidates should possess a first degree with considerable years teaching experience since qualification. All appointees will be expected to assist with departmental administration as and when required and also provide a service to the community whenever possible. Salary scales: Senior Lecturer N7,764 to N8,724 per annum (£6,161 to £6,923 per annum sterling). Lecturer I N6,444 to N6,984 per annum (£5,114 to £5,542 per annum sterling). (£1 sterling equals N1.26). Fringe benefits include pension scheme or contract addition of salary (partly taxable). There may be salary supplementation of salary for Senior Lecturers of £2,892 per annum (sterling) for married appointees and £726 per annum (sterling) for single appointees (presently under review and free from all tax) and provision of children's education allowances and holiday visit passages. Lectureships will not attract the supplement. The appointment may be either on fixed term normally of two years contract renewable by mutual agreement or till retiring age of sixty. Family passages, biennial overseas leave, car allowance and pension scheme, partly furnished accommodation at low rental. Detailed applications (two copies) with curriculum vitae and naming three referees should be sent direct to the Registrar, Ahmadu Bello University, Zaria, Nigeria, by February 27, 1979. Applicants resident in U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. 9184(A)

THE UNIVERSITY OF LIVERPOOL
CYTOGENETICS UNIT
SCIENTIFIC OFFICER (CYTOGENETICIST)

Applications are invited from Science graduates for a basic grade post on the Whitley Council "A" scales in this unit which provides the Cytogenetics Service for the Mersey Regional Health Authority.

Experience in human cytogenetic techniques/tissue culture is desirable.

Salary within a range £3,486 to £4,275 per annum depending on qualifications and experience. Applications in writing together with two references should be made as soon as possible and no later than Friday, February 9, to The Registrar, The University, P.O. Box 147, Liverpool L69 3BX.

UNIVERSITY OF SOUTHAMPTON

SHIP SCIENCE

Vacancies for a

MATHEMATICIAN/ PHYSICIST

and a

NAVAL ARCHITECT

Applications are invited to fill two posts to continue research into the capsizing of ships This work is being sponsored by the Ministry of Defence for a further period of three years

The first appointment, to take effect immediately, is for a postdoctoral Research Fellow who should be an Applied Mathematician or Theoretical Physicist with experience in hydrodynamics An additional knowledge of the mechanics of non-linear systems would be advantageous

The second appointment, to take effect after July 1, 1979, is for a Research Assistant who should have a good degree in Naval Architecture with a knowledge of ship dynamics and hydrodynamics

Salaries will depend on age and experience but will be in a range up to £4,882 for the Fellowship and £3,882 for the Assistantship U S S superannuation benefits apply

Further details may be obtained from D A S Copland, The University, Southampton SO9 5NH to whom applications giving a curriculum vitae and the names of two referees should be sent not later than February 12 Please quote reference No 181/R/Na. 9148(A)

UNIVERSITY OF MELBOURNE

Australia

RESEARCH FELLOW GRADE II (LIMITED TENURE) IN PHYSICAL OCEANOGRAPHY OF THE SOUTHERN OCEAN

in the

DEPARTMENTS OF MATHEMATICS AND METEOROLOGY

A position has been created, in conjunction with a New Development Programme for Antarctic Studies and Resources, for a Research Fellow to work jointly in the Mathematics and Meteorology Departments of this University primarily on the development of a model of the Southern Ocean circulation with some emphasis on sea/air/ice interactions.

The candidate should preferably have a background in physical oceanography and some knowledge of numerical modelling. Applicants should also state any field experience they may have

SALARY $A15,179 to $A19,940 per annum.

Further information, including details of application procedure and conditions of appointment, is available from the Registrar, University of Melbourne, Parkville, Victoria, 3052, Australia or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications close on *March 15, 1979.* 9179(A)

THE AUSTRALIAN NATIONAL UNIVERSITY

THE JOHN CURTIN SCHOOL OF MEDICAL RESEARCH

RESEARCH FELLOWS

(Several positions)

Applications are invited from candidates who hold a Ph D degree or who hold medical, dental or veterinary qualifications and have had some research experience.

The Departments in the School and their fields of research are.

Biochemistry (Head, Professor F. Gibson, F.A.A., F.R.S.): Biochemical and genetic studies on bacterial membranes, oxidative phosphorylation, active transport, NADH dehydrogenase, ubiquinone biosynthesis Kinetic mechanism and regulation of enzymes concerned in aromatic biosynthesis.

Clinical Science (Acting Head, Dr M A Denborough). Biochemical and pharmacological studies on membrane function in relation to human disease Emphasis at present is on calcium, cyclic nucleotide and prostaglandin metabolism, asthma, diseases of muscle, malignant hyperpyrexia, platelet function, atherosclerosis, thrombosis and haemostasis, osteogenesis imperfecta, clinical pharmacology and clinical immunology

Experimental Pathology (Acting Head, Dr W. J Cliff): Research in this Department, which traditionally combines morphological and biochemical studies, has been on *cardiovascular disease*, in terms of the earliest occlusive lesions, endothelial permeability and experimental arterial grafting; topography, differentiation and regression of vascular beds, *neoplasia*, in terms of cyclic nucleotide metabolism and levels in body fluids for cancer diagnosis, and the effects of ionizing radiation on mammalian tissues, and *degenerative diseases* with the search for a hormone for fibrous tissue contraction with the induction and treatment of arthritis and with the study of both local and systemic changes associated with inflammation; the mechanisms of cellular and subcellular motility, using cinephotomicrographic, fine structural, cytochemical and biochemical techniques.

Human Biology (Head, Dr R L. Kirk): Human population genetics; disease susceptibility and red cell metabolism and function.

Immunology (Head, Professor B. Morris, F.A.A.): Genetic basis of disease resistance in economic livestock, physiological studies of the immune response, transplantation biology, immunobiology of cancer, tolerance, foetal-maternal interactions, physiology of the lymphoid apparatus, immunological studies of cattle chimeras.

Medical Chemistry Group (Head, Dr D J. Brown): The Group studies the synthesis, properties, stereochemistry, and biological activity of heterocycles (carbocyclic molecules including nitrogen or another foreign atom) related to natural pyrimidines, pteridines, or purines; the equilibria involving metal ions and cell constituents such as amino acids or proteins, and the spectroscopic properties of simple molecules Attention is being given to the therapeutic applications of such research.

Microbiology (Head, Professor G. L. Ada, F A.A.): Reactions of antigens with lymphoid cells, particularly T cell recognition of membrane antigens, structure, synthesis and function of viral nucleic acids; tissue cultural studies of the growth and genetics of pox, polio and other viruses; immune defence mechanisms against viruses, bacteria and tumours, immunogenetics, the chemistry, antigenic properties and epidemiology of influenza virus, epidemiology and adaptation of arboviruses; activities of lymphocyte sub-populations and responses to modified antigens, properties and roles of histocompatibility antigens.

Parmacology (Head, Professor D R. Curtis, F.A.A., F.R.S.): Neuropharmacology of central synaptic transmission, including that of central pain pathways, neurochemistry of central amino acid receptors.

Physical Biochemistry (Head, Professor L. W Nichol). Physical and chemical characterisation of biological macromolecules, interacting protein systems including studies on subunit assembly, self-associations and acceptor-ligand binding, amino acid sequence of lactoferrin; comparative studies of protein denaturation and hydration, physical and kinetic studies on sulphatases and related enzymes; molecular conformation and structure-activity relations of drugs and neurotransmitters, enzyme transition state analogues.

Physiology (Head, Professor P. O Bishop, F.A.A., F R.S.); Sensory neurophysiology especially in relation to vision and visual optics, neurohistology and the biophysics to muscular contraction.

Appointments normally will be for two years but in exceptional circumstances may be for three years and extended to a total period of five years

It is hoped that the successful candidates will be able to take up their appointment in the first half of 1979.

APPLICANTS SHOULD ARRANGE FOR REPORTS FROM THREE ACADEMIC REFEREES TO BE SENT TO THE UNDERSIGNED IN SUPPORT OF THEIR APPLICATION.

CLOSING DATE· *FEBRUARY 15 1979.*

Commencing salary will be in accordance with qualifications within the range $A15,179 to $A19,813 per annum Current exchange rates $A1 58NP $US1 14.

A salary loading of up to $A5,000 per annum may be paid to an applicant holding appropriate medical qualifications.

OTHER CONDITIONS

Reasonable appointment expenses are paid. Superannuation benefits are available for applicants who are eligible to contribute Assistance with housing is provided for an appointee from outside Canberra.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time

Further information may be obtained from the Heads of the respective Departments.

P O Box 4,
Canberra, ACT 2600,
Australia

G. E. Dicker
Academic Registrar

free university amsterdam

The **Faculty of Medicine** has a vacancy for a

READER ("Lector") in Histology.

Applicants should have practical teaching experience in at least a part of histology as well as research experience, preferably in the histofysiology of the immune response

The Free University was founded in 1880 as a private institution and is now a fully state subsidized private University

The preamble to its charter speaks of the Christian idea of service as the university's guiding principle.

It would be appreciated if candidates would express their attitude towards this principle in their application

Non-Netherlands applicants are expected to acquire a reasonable command of the Dutch language within about two years

Suggestions concerning qualified candidates for this function should be submitted to the chairman of the nomination committee, Prof Dr A H M Lohman, (Van der Boechorststraat 7, 1081 BT Amsterdam, tel 020 - 548 27 23), who is also willing to give further information

---

Applications, accompanied by a curriculum vitae, a list of publications and three names of persons, acquainted with the applicant's academic and professional standards, should be sent within four weeks after appearance of this announcement to Dienst Personeelszaken (Personnel Department), Vrije Universiteit, De Boelelaan 1105, postbox 7161, 1007 MC Amsterdam, quoting reference number 219 - 2628

9240(A)

VU

Wellcome

Biochemist/Enzymologist

Beckenham, Kent

Wellcome Reagents Ltd—a rapidly growing part of the international, British-owned Wellcome Foundation Ltd.—researches, manufactures and markets biological diagnostic products for medical and veterinary laboratory use world-wide.

We seek a scientist to join a small team working on enzyme-based immunoassay systems for the analysis of clinical samples in the Research and Development section of Wellcome Reagents Ltd.

Candidates should have some postgraduate experience including work in the field of enzymology (particularly purification and assay) and should be prepared to contribute actively to the development of novel diagnostic systems.

Salary offered will depend on qualifications and ability but is likely to be around £5000 initially, within the range £3651 to £5522 or £4997 to £7859. There is considerable scope for job development as the organisation continues to grow. The post is based at The Wellcome Research Laboratories, situated in pleasant parkland surroundings, within easy reach of Bromley and Beckenham, about 12 miles from Charing Cross. Conditions of employment are attractive and include 4 weeks' holiday, company pension fund, sick pay scheme, subsidised canteen and assistance with relocation expenses, where appropriate.

Please write, giving details of relevant experience and qualifications, to
R V Sutton, Personnel Officer,
The Wellcome Research Laboratories,
Langley Court, Beckenham, Kent BR3 3BS,
quoting reference number U.978.

CSIRO AUSTRALIA
Research Scientist
Division of Land Use Research
Canberra, Act

CSIRO has a broad charter for research into primary and secondary industry areas The Organisation has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia

Field: Soil Science (Soil Hydro-Geography)

General: The Division is engaged in research on land and water resources and their evaluation for various uses. Its current research is concerned, *inter alia,* with development of methods of resource surveys as well as methods of predicting, from resource data, biological productivity and water flow and quality. The Division is therefore particularly interested in interpretation of soil data, which can be acquired through surveys and associated laboratory studies and presented in form of maps, in terms of hydrological properties needed to determine water balance aspects of the hydrological cycle and to estimate water availability to plants.

Duties The appointee will participate in collaborative research concerned with resource surveys and use of survey information for evaluating land capability for agricultural, pastoral and forestry uses and for engineering structures He or she will undertake the development of methods of determining, from survey and laboratory data, hydrological soil characteristics which will allow better quantitative prediction of hydrological cycle parameters, particularly through-drainage, run-off and soil water available to plants

Qualifications: Ph D or equivalent qualifications together with interest and experience in research on both soil physical and soil survey problems

Salary: Research Scientist or Senior Research Scientist $A14,829 to $A21,543 p a Appointment at higher level may be considered for suitably qualified candidates

Tenure Indefinite with superannuation.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 618/453 should reach—

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 16th February 1979

Applications in U S A and Canada should be sent to—The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N W, Washington, D.C, 20036, U.S A. 9207(A)

LA TROBE UNIVERSITY
Melbourne, Australia
School of Biological Sciences
DEPARTMENT OF BIOCHEMISTRY
LECTURER

Applications are invited for this post from suitably qualified biochemists to teach in undergraduate courses, and to carry out research in co-operation with existing members of staff. Applicants should have a Ph.D in Biochemistry and relevant teaching experience The appointment will be for a fixed term of up to three years.

SALARY $A15,786 to $A20,737.

Further information and application forms are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF Applications marked confidential and quoting reference number 150/14/19 close *February 9, 1979.* 9153(A)

UNIVERSITY OF MIAMI
DEPARTMENT OF BIOCHEMISTRY
POSTDOCTORAL RESEARCH ASSOCIATE

Applications are invited for the position of Research Associate in the Department of Biochemistry, University of Miami School of Medicine A biochemist with experience in immunological techniques and cell biology would be preferred Duties will include studies on procedures for enzyme modification that result in products with increased therapeutic usefulness [see, for example, *Trends in Biochemical Sciences* (1978) 3, 79–83]

Salary according to experience Only highly motivated individuals need apply.

Further information from and applications to Dr J. J Marshall, Department of Biochemistry D4-9, University of Miami School of Medicine, P.O. Box 016960, Miami, Florida *33101.*

Applications should include the names of three referees. 9236(A)

Royal Botanic Gardens, Kew

Botanist

...undertake taxonomic research on palms

The scientific work of the Royal Botanic Gardens is concerned with the classification, growth, structure and uses of plants, utilising the collections of preserved material in the Herbarium and Museums, and the unique collection of living plants in the gardens.

The Herbarium, contains about 5 million specimens, and is supplemented by a comprehensive library specializing in taxonomic literature. Included in this Herbarium is a rich collection of the important, yet often neglected, tropical family Palmae. In recent years, the palm specimens, including large sheets and carpological material, have been re-housed and the botanist appointed will curate this specialised collection and undertake taxonomic research on the Palmae.

Candidates, normally aged under 32, should have a good honours degree, or equivalent in Botany. At least 4 years relevant postgraduate experience is essential; experience of palms, particularly if gained in the field, is highly desirable.

Appointment as Senior Scientific Officer (£5425-£7175) with starting salary according to qualifications and experience. Promotion prospects. Non-contributory pension scheme. *Please quote ref: SB/17/AH.*

■ *For application details please see below.*

Home Office, Birmingham

Scientists

...forensic Studies of Documents

Scientists are required in the Document Section of the Forensic Science Laboratory, which carries out investigations for the Police relating to questioned documents and handwriting.

The successful candidates will be concerned with photographing documents by infra-red, ultra-violet and luminescence methods and the examination of paper, inks, handwriting and typescript for evidence. Initially, whilst training, they will assist senior colleagues, but will ultimately prepare reports and attend court hearings as expert witnesses.

Candidates, normally aged under 27, should have a good honours degree or equivalent in a scientific subject. Appointment as Scientific Officer (£2840-£4410) with starting salary according to qualifications and experience. Promotion prospects. Non-contributory pension scheme. *Final year students will not be considered. Please quote ref: SB/21/LA.*

For further details and an application form (to be returned by 9 February 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). *Please quote appropriate ref.*

ALL THESE POSTS ARE OPEN TO MEN AND WOMEN.

9204(A)

Science Group
CIVIL SERVICE

RESEARCH ASSISTANT

A graduate chemist or biochemist with an interest in biochemical engineering is required for a pilot study of animal feed protein production from activated sludge. The appointment will be for one year, and the person appointed will be responsible for running the pilot plant and carrying out various analytical procedures.

The salary will be in the range of £2,800 to £3,400 depending on qualifications and experience.

Applications, including the name and address of one referee, should be sent to Dr R. A. Grant, 41A Springfield Road, Parkstone, Poole, Dorset.

9188(A)

MEDICAL RESEARCH COUNCIL

CELL BIOPHYSICS UNIT

There is likely to be, in the immediate future, a vacancy for a postgraduate research student to undertake work in one of the Unit's areas of activity (especially neurofilaments, muscle and membrane biochemistry, muscle structure and function). Remuneration and conditions as for normal Research Council studentships.

Apply in writing, together with the names and addresses of two referees, as soon as possible to: Professor M. H. F. Wilkins, CBE, FRS, Cell Biophysics Unit, 26-29 Drury Lane, London WC2B 5RL.

9187(A)

THE UNIVERSITY OF THE WEST INDIES—JAMAICA

Applications are invited for the following posts:

RESEARCH FELLOW (Physics)

Science Education Centre

Applicants should at least hold a first degree in Physics and have professional training for teaching. Preference will be given to those with experience of teaching in the West Indies. In addition it will be an advantage to have experience in testing, evaluation and assessment.

LECTURER/ ASSISTANT LECTURER in Inorganic Chemistry

The appointee will be expected to play a major role in the teaching and organisation of the Chemistry courses and to contribute to the research programme of the Department.

LECTURER IN ZOOLOGY (Marine/Fisheries Biology)

The appointee will be expected to assist in the development of programmes of research and teaching in marine biology and fisheries biology. The appointee must be able to take up the post not later than September 1, 1979. Candidates who responded to an earlier advertisement (March/April 1978) need not re-apply.

LECTURER/ ASSISTANT LECTURER in Botany

Preference wil be given to applicants who possess a first degree with majors in Botany and hold postgraduate qualifications in Plant Pathology. The appointee will be required to take up duties as soon as possible.

Salary scales: Research Fellow/ Lecturer J$8,913 to J$13,917 p.a.; Assistant Lecturer J$7,236 to J$7,926 p.a. (£1 sterling=J$3.46). F.S.S.U.; Study and Travel Grant. Unfurnished accommodation will be let by the University at a rental of 10% of salary or a housing allowance of 20% of salary will be paid. Family passages.

Detailed applications (2 copies) with curriculum vitae and naming three referees should be sent as soon as possible direct to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica.

Applicants resident in the U.K. should also send one copy to 90-91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address.

Postdoctoral Research Fellows

Division of Land Resources Management Alice Springs, NT and Deniliquin, NSW

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field: SOCIAL SCIENCE

General: The Division has problem oriented research programs concerned with the environmental, societal, economic and technological implications of land use in range, agricultural, forested and near urban areas, and with the development of methods for processing and communicating data to assist land use decision making.

As a further expansion of our activities in these areas, we wish to appoint social scientists to join multi-disciplinary, but predominantly biological, research teams at Alice Springs and Deniliquin. These teams are concerned with research into the management of and and semi-and rangelands of Australia

We are seeking two quantitative scientists with research experience (Ph.D or equivalent) in at least one of the following fields:

Social Psychology
Environmental Economics
Quantitative Sociology
Human Geography

who will interact with research in progress at Deniliquin and Alice Springs The appointees will also interact with other social scientists located at Divisional headquarters in Perth, W.A.

Duties

Alice Springs—Ref No. 284/86

In association with technological scientists, the appointee will research social, economic and land tenure problems associated with the management of and lands

Deniliquin—Ref. No. 284/89

The appointee will research the way in which the pastoralists' perceptions of the land resources they manage is influenced by biological, economic, political and social variables. This research will relate to existing socio-economic research which is identifying the effect of land tenure and administration on pastoral management and will assist in developing processes which will improve and land management.

Salary: Research Scientist or Senior Research Scientist $A14,829 to $A21,543 p a An outstanding applicant may be offered appointment at a higher level

Tenure: A fixed term of two to five years (negotiable)

Applications IN DUPLICATE, stating FULL personal and professional details, the names and addresses of at least two professional referees, and QUOTING THE APPROPRIATE REFERENCE NUMBER(S) should reach. The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maltravers Street, London WC2R 3EH by 16th February 1979.

Applications in U S A and Canada should be sent to: The Counsellor (Scientific) Embassy of Australia, 1601 Massachusetts Avenue N W, Washington, D C 20036 9211(A)

LECTURER IN PHYSIOLOGY

Preference will be given to applicants with research interests in endocrinology, reproductive physiology, fetal or developmental physiology *March 31, 1979*

Salary $A15,179 to $A19,940 per annum Other Benefits Superannuation, housing assistance, travelling and removal expenses.

Additional information and application forms are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. 9183(A) appointment of

Director

(male or female)

Brain Metabolism Unit

The Council invites applications for the post of full-time Director at the MRC Brain Metabolism Unit in Edinburgh The successful applicant will be a person of high scientific standing (with or without a medical qualification), with an established reputation as an original scientific investigator The Unit is at present engaged in basic neurobiological, and clinical research relevant to psychiatry and neurology The Council wishes the psychiatric interests of the Unit to be maintained The title and programme of the Unit will be decided by the Council in the light of the research interests of the new Director

The Unit is mainly housed in research accommodation of approximately 4,000 sq ft (nett) in the Department of Pharmacology of Edinburgh University and within the Royal Edinburgh Hospital An active research team is already in post· the size of the Unit will be a matter for discussion between the Director and the Council The Director will be responsible for maintaining the strong links already existing with the University of Edinburgh

The salary for a medically qualified Director, for whom an honorary clinical contract at consultant level will be sought, will be on the MRC clinical scale, equivalent to NHS consultant grade; if an honorary contract is not appropriate, the salary will be within the range for the Council's Special Appointments Grade, which is equivalent to the University professional range

MRC

Further information may be obtained from Miss R Withnall, 20 Park Crescent, London W1N 4AL Applications should be submitted to the Secretary of the Council at the same address, not later than 19 February, 1979

Agrochemical
Field Evaluation

We are looking for a graduate with a good honours degree in Agriculture or related subjects to join a young and enthusiastic team conducting early stage field evaluation trials with new agrochemicals. Applicants should have post graduate experience in field experiments together with practical experience in arable husbandry. The person appointed will be based at Jealotts Hill Research Station, Bracknell, Berkshire but should be willing to travel extensively planning and organising the work of field teams based in the main areas of the U.K.

We offer good salaries and fringe benefits including membership of the ICI Pension Fund and Profit Sharing Schemes. A Staff Restaurant and Recreation Club are on site.

If you are interested in this vacancy please write for an application form to: Mr S R Stephenson, ICI Plant Protection Division, Jealott's Hill Research Station, Bracknell, Berks.

CHARING CROSS HOSPITAL (FULHAN

MEDICAL PHYSICS DEPARTMENT

BASIC GRADE PHYSICIST

Applications are invited for the above vacancy in this teaching hospital. Applicants should have a first or second class Honours degree in Physics. The duties will be mainly concerned with the measurement and application of radiation
in the medical field. Applicants should also have a basic knowledge of physics, outside the field of ionising radiations. Experience in the use of computers would be an advantage.

Previous experience in hospital physics is essential.

Salary in accordance with Whitley Council regulations, within the range £4,152 to £5,253 including London Weightin

Application forms and further information available from District Personnel Department, Charing Cross Hospital, Fulham Palace Road, London W6 9HH. Tel: 01-748 2040, Ext. 2997.

Closing date for receipt of applications February 8, 1979.

9247(A

PLANT MOLECULAR BIOLOGIST

BROOKHAVEN NATIONAL LABORATORY

Position now available for plant scientist to conduct research in molecular biology Candidates must have a background in the plant sciences and demonstrated experience in the area of molecular genetics. Research initiated by the investigator may be at a fundamental level but must be directed toward the U S. Department of Energy's long range goals of increasing biomass productivity. This would include basic research on cellular or genetic mechanisms that control plant growth, productivity, and response to the environment

Applicants should submit a curriculum vitae (including list of publications), brief research proposal; and the names of three references to:

H. Z Kondratuk
Biology Department
Brookhaven National Laboratory
Associated Universities, Inc.
Upton, L.I., N.Y. 11973

An Equal Opportunity Employer M/F

9168(A)

Experimental Officer

Biochemistry Department

A Biochemist is required to work within the Natural Products Section of our Biochemistry Department The job will involve the development of biochemical screens to evaluate potential anti-inflammatory agents from natural sources and the subsequent follow up of active leads. The successful candidate will be expected to have a degree or H.N C. in biochemistry and experience of the pharmaceutical industry would be an advantage but not essential.

Our modern research laboratories are situated in pleasant surroundings, but within easy reach of main road and rail routes Conditions of service, salary and assistance to married staff in moving house are designed to attract and retain staff of high calibre

Please write giving details of qualifications and experience to:
Mrs D Bass,
Assistant Personnel Officer,
Imperial Chemical Industries Limited, Pharmaceuticals Division, Mereside Research Laboratories,
Alderley Park,
Nr. Macclesfield,
Cheshire.

9216(A)

British Museum Research Laboratory, London

GEOLOGIST

The British Museum comprises the national collections of Antiquities and Ethnography and of Prints and Drawings Its purpose is to advance learning by the provision of materials and facilities for research, and by encouraging the study of history, archaeology and art The Research Laboratory provides services and advice to other Departments of the British Museum in connection with the scientific examination and dating of objects in the departmental collections The Laboratory is equipped with excellent research facilities

The geologist appointed will undertake petrological examinations of ceramics and stone artefacts with a view to establishing the origin of the raw materials used, and the methods of ceramic manufacture This will involve participation in research projects using petrological examination, neutron activation analysis and scanning electron microscopy.

Candidates, normally aged under 30, should have a good honours degree or equivalent in geology and at least 2 years' relevant postgraduate experience which must include a significant element of petrology

Appointment as Higher Scientific Officer (£4,560 to £5,910) with starting salary according to qualifications and experience Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by 9th February, 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB or telephone Basingstoke (0256) 68551 (answering service operates outside office hours) Please quote ref.: SB/7/DJA.

CSIRO AUSTRALIA

Postdoctoral Research Fellow

Division of Land Resources Management Alice Springs, NT

CSIRO has a broad charter for research into primary and secondary industry areas The Organization has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field: RANGELAND ECOLOGY

General: The Division with headquarters in Perth, W A., is involved in research on the broad aspects of management of range, agricultural and forested lands in Australia. The Rangelands Research Program is based at Alice Springs, NT and Deniliquin, NSW and is responsible for research on the arid and semi-arid lands used for grazing, national parks, mining, and by Aborigines

Duties: The appointee will work in a multi-disciplinary team with five other professional scientists and will be expected to develop a research program on the ecology of key rangeland plant species.

Qualifications: A Ph.D or equivalent research experience in any field of quantitative plant ecology.

Salary: Research Scientist or Senior Research Scientist: $A14,829 to $A21,543 p a. An outstanding applicant may be offered appointment at a higher level.

Tenure: A fixed term of two to five years (negotiable)

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 284/87 should reach:

The Personnel Officer, Australian Scientific Liaison Office,
Canberra House, 10-16 Maltravers Street, London WC2R 3EH,
by 16th FEBRUARY 1979

Applications in U S.A. and Canada should be sent to:

Virologist and Research Officer

NIBSC is a multidisciplinary Institute responsible for the testing and control of biological substances used in medicine and is also a WHO International laboratory for biological standards The work of the Institute is well supported by research.

We wish to appoint a Virologist (scientist) and a Research Officer to join the Institute's Division of Viral Products.

Virologist

(Ref 0178)

The Scientist appointed will work in the field of hepatitis and/or rabies. The successful candidate will have at least 3 years' postdoctoral experience in virology or a closely related field Preference will be given to those with research experience in either the Immunochemistry of viruses or viral biochemistry.

Salary will be on grades analogous to those for university lecturers and the tenure of the appointment will depend on the experience and qualifications of the successful candidate.

Research Officer

(Ref 0180)

The Research Officer will work in the field of the standardisation and control of rabies vaccines in close association with a scientist. He or she should have had at least two years' relevant postgraduate experience in virology. Preference will be given to candidates who have previous experience of work with rabies or other highly pathogenic viruses Candidates should possess a degree or equivalent in the biological sciences

Salary, depending on age and experience, on the scale £3,615 to £5,256, including London Weighting.

Both posts are superannuable.

Write or telephone for an application form and further details, quoting the post reference number to the Personnel Officer, National Institute for Biological Standard and Control, Holly Hill, Hampstead, London NW3 6RB. Telephone 01-435 2232, Ext. 211.

NEWCASTLE AREA HEALTH AUTHORITY (TEACHING)

ROYAL VICTORIA INFIRMARY

CYTOGENETICIST

SCIENTIFIC OFFICER, BASIC GRADE

Graduate required immediately for work in active cytogenetics service laboratory involved in all aspects of diagnostic cytogenetics including leukocyte culture, amniotic fluid cell culture, fetal cultures, and bone marrow analysis. Previous experience preferable but not essential.

For further information please contact Professor D. F. Roberts, Telephone 0632 : 25131, extension 658.

Salary on Whitley Council P.T.A. Scales:

Probationary 1st or 2nd Class Honours degrees:
£3,486 by 5 increments to £4,275 per annum.

Other degrees:
£2,991 by 9 increments to £4,275 per annum.

Post-Probationary Scale:
£3,798 by 9 increments to £4,899 per annum.

Applications giving full personal details, together with the names and addresses of two referees, should be sent to the Senior Administrative Assistant (Personnel), Royal Victoria Infirmary, Newcastle upon Tyne NE1 4LP. Closing date January 29, 1979. Quote Ref. No. 79/5.

9159(A)

Microbiologist £2,839-£6,898

Applications are invited for a pensionable post in the Department of Agriculture's Agricultural and Food Bacteriology Division, Newforge Lane, Belfast.

The successful candidate will be expected to undertake research and investigational work connected with the microbiology of foods and may also be required to undertake lecturing duties in the Faculty of Agriculture and Food Science, Queen's University, Belfast.

Appointment may be at Senior Scientific Officer, Higher Scientific Officer, Scientific Officer level.

SENIOR SCIENTIFIC OFFICER

Over 25 and under 32 years of age on 31st December, 1979 with a 1st or 2nd class Honours Degree in an appropriate Science subject, Agricultural Science, Food Science or Agriculture, and at least 4 years appropriate postgraduate experience.

HIGHER SCIENTIFIC OFFICER

Under 30 years of age on 31st December, 1979 with an Honours Degree as above and at least 2 years appropriate postgraduate experience in Microbiology.

SCIENTIFIC OFFICER

Under 27 years of age on 31st December, 1979 with an Honours Degree as above. Where the applicant has no relevant postgraduate experience in Microbiology, preference may be given to those whose degrees have Microbiology as the main subject.

Exceptionally applications may be considered from candidates over the age limits who have specialised experience.

The Civil Service Commissioners may decide to interview only those applicants who appear from the information available (including level of academic attainment and relevant experience) to be best qualified.

SALARY SCALES

Senior Scientific Officer — £5,154-£6,898
Higher Scientific Officer — £4,101-£5,448
Scientific Officer — £2,839-£4,415

Grading and starting salary will be related to qualifications and experience.

Please write or telephone for an application form quoting job reference SB 34/79/N to the Civil Service Commission, Rosepark House, Upper Newtownards Road, Belfast BT4 3NR (telephone Dundonald 4585 Ext 257). Completed forms must be returned to arrive not later than 1st February, 1979. 9157(A)

NORTHERN IRELAND CIVIL SERVICE

THE UNIVERSITY OF MANITOBA

invites applications and nominations for the position of

DEAN OF THE FACULTY OF SCIENCE

The Faculty of Science at The University of Manitoba has a complement of 180 faculty and 90 support staff. Its twelve departments and units span the Biological, Mathematical and Physical Sciences; they offer a full range of undergraduate Science programmes for approximately 2,100 students enrolled in the Faculty, courses for a large number of students from other faculties and schools and M.Sc. and Ph.D. programmes for about 280 graduate students.

Candidates should have achieved distinction as scholars in a major field of Science, have a commitment to advancing higher education in Science and have strong leadership ability. Relevant administrative experience and knowledge of the Canadian educational system would be assets.

The appointment is expected to commence September 1, 1979, and will be for a renewable term of normally five to seven years.

Please address responses to:

Provost R. A. Johnson,
Chairman,
Selection Committee for Dean of the Faculty of Science,
Room 202, Administration Building,
The University of Manitoba,
Winnipeg, Manitoba,
Canada, R3T 2N2.

Applications, nominations and suggestions will be received until March 15, 1979. 9171(A)

CSIRO AUSTRALIA

Postdoctoral Research Fellow

Division of Mineral Chemistry
Port Melbourne, Victoria

CSIRO has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

Field: SURFACE CHEMISTRY OF COAL

General: The work will be centred at the laboratories of the Division of Mineral Chemistry in Melbourne (Port Melbourne) but will involve collaboration with the CSIRO Fuel Geoscience Unit in Sydney (North Ryde). A period will be spent in Sydney at the Fuel Geoscience Unit and coal washeries on the NSW coal-fields.

Duties: To study the surface properties of Australian black coals in relation to the behaviour of coal constituents during the upgrading of coal by froth flotation.

Qualifications: Ph.D in Chemistry or equivalent. Experience in surface chemistry or applied colloid science will be an advantage.

Salary: Within the range Research Scientist to Senior Research Scientist: $A14,829 to $A21,543 p.a.

Tenure: 12 months' appointment with the possibility of extension.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 430/390 should reach—

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 16th February 1979.

Applications in U.S.A. and Canada should be sent to—The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A. 9210(A)

Nature Conservancy Council

FIELD UNIT LEADER

SCOTLAND (Senior Scientific Officer Level)

Salary Scale: **£5,154—£6,898**

Applications are invited for the post of Field Unit Leader for Scotland, based at the Nature Conservancy Council's Headquarters for Scotland, in Edinburgh.

Background

The function of the FIELD UNIT is to develop a co-ordinated programme of survey and monitoring in SCOTLAND in conjunction with Country HQ, regions and the Chief Scientist by carrying out appropriate survey and monitoring projects and to synthesise and interpret the results so as to facilitate maximum use of the information by all staff within the organisation.

The Post

The successful applicant should be a biologist with considerable experience of ecological survey work who will be required to lead the newly formed Field Survey Unit in Scotland (outlined above). The work will involve surveys of the flora and fauna of particular habitats, assessing the impact of developments and monitoring changes in the environment.

Age and Qualifications

Preference will be given to candidates with experience of survey methodology and numerical data processing and with a wide knowledge of British vegetation types.

Candidates should have a *first or second class honours degree* or equivalent in biology, botany, zoology, geology or geography and should normally be aged at least 25 and under 32 years of age and have at least 4 years relevant post-graduate experience.

This post will entail extensive travelling and possession of a current driving licence is therefore essential.

Application forms and further details are available from Recruitment Section, Nature Conservancy Council, Godwin House, George Street, Huntingdon, Cambs PE18 6BU (Tel. 0480 56191). Closing date for completed application forms is February 16, 1979. Interviews will be held in March 1979. 9203(A)

Northern Ireland Forensic Science Laboratory

Scientific Staff

Applications are invited for the following pensionable posts in the Northern Ireland Forensic Science Laboratory, Newtownbreda Road, Belfast.

The successful candidates will join a team of scientists engaged in the scientific investigations of crime throughout Northern Ireland. The work is interesting and varied and offers wide scope for developing interests in the varied aspects of forensic science.

METALLURGIST

(Higher Scientific Officer)
£4101 - £5448
(Ref SB 28/79/N)

Applicants must be under 30 years of age at 31 December 1979 and possess:
(a) a 1st or 2nd class honours degree in Metallurgy; or
(b) an equivalent qualification acceptable to the Civil Service Commissioners.

Candidates must have at least 2 year's postgraduate experience in research or industry.

DOCUMENT EXAMINER

(Scientific Officer)
£2839 - £4415
(Ref SB 29/79/N)

Applicants must be under 27 years of age at 31 December 1979 and possess:
(a) a 1st or 2nd class honours degree in a relevant scientific subject; or
(b) an equivalent qualification acceptable to the Civil Service Commissioners.

The officer appointed will be involved in the comparison of handwriting and typewriting and the examination of signatures and documents to detect forgery, alterations, etc. Previous experience in this field may be an advantage.

SCIENTIFIC OFFICER

£2839 - £4415
(Ref SB 30/79/N)

Applicants must be under 27 years of age at 31 December 1979 and possess:
(a) a degree in pure or analytical chemistry; or
(b) an equivalent qualification acceptable to the Civil Service Commissioners.

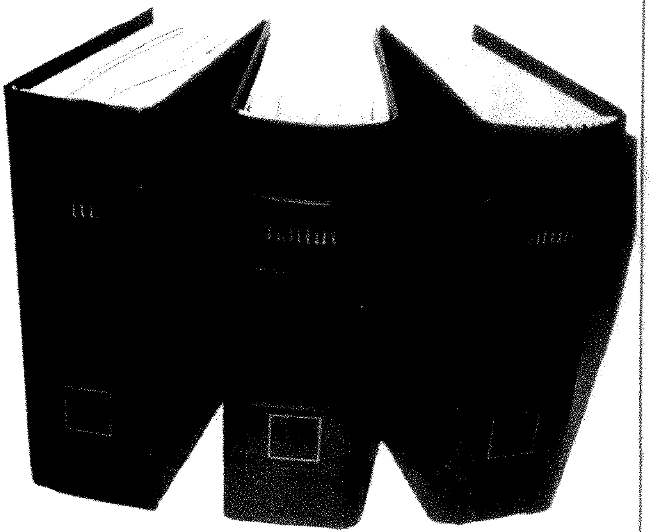
Exceptionally, applications may be considered from candidates over the age limits who have specialised experience.

Starting salary will be related to qualifications and experience.

There are promotion prospects to Higher Scientific Officer £4101-£5448, Senior Scientific Officer £5154-£6898 and Principal Scientific Officer £6609-£8461.

Please write or telephone for an application form quoting the appropriate reference number to the Civil Service Commission, Rosepark House, Upper Newtownards Road, Belfast BT4 3NR (Telephone Dundonald 4585 ext 256). Completed forms must be returned to arrive not later than 1 February, 1979. 9238(A)

Nature Binders



Keep your copies of Nature protected in durable black PVC binders:
* 20 plastic retention strips mean no loose parts, wire, or complex loading systems
* title blocked in gold on spine
* panel on spine for your own references
Each binder is designed to take two volumes of Nature; three binders will serve for a year.

Prices (including postage):
UK £3.00 each, three for £8.00
Rest of World US $6.00, three for US $16.00
Orders with correct remittance should be sent to:
Nature, Circulation Department,
Macmillan Journals Ltd,
Brunel Road, Basingstoke,
Hampshire RG21 2XS, England.
Registered No: 785998 England
Registered Office: 4 Little Essex Street,
London WC2R 3LF

nature

CSIRO AUSTRALIA

Division of Applied Geomechanics Syndal, Victoria

CSIRO has a broad charter for research into primary and secondary industry areas The Organisation has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

1. Research Scientist

Ref. No. 920/247

Field: Slope stability applied to mining.

General: The Division is engaged in research on the engineering properties of soils and rocks and the application of this research in the fields of coal and metalliferous mining and urban, regional and marine geotechnology. The Division has its headquarters and main laboratories at Syndal near Melbourne Other staff are located in Adelaide, Sydney and mining areas in New South Wales and Queensland.

Duties: To supervise a research team engaged on studies related to surface mining. Initially the appointee will be required to conduct research aimed at defining the causes of slope failure in surface coal mines and predicting the mechanisms of failure at greater mine depths. Research will involve studies of the geology, material properties and stress in coal and adjacent strata together with the development of modelling techniques for surface coal mines.

Qualifications: A PhD degree or equivalent qualification in civil engineering, mining engineering or engineering geology, together with demonstrable research ability in one or more of the following fields: geology, hydrology, slope kinematics, modelling and behaviour monitoring

Location: The appointee will be located at Syndal, Victoria; however extensive field trips to the Bowen Basin, Queensland, and Hunter Valley, NSW, are envisaged.

Salary: Appointment will be made within the ranges of Senior Research Scientist or Principal Research Scientist · $A18,819-$A25,354 per annum

Tenure: Indefinite with superannuation

2. Postdoctoral Research Fellow

(2 positions)

POSITON 1—Ref. No. 920/245

Field: Engineering geology.

Duties: To initiate research into the structural aspects of roof instability in coal mines using geological and engineering techniques. Structural geology relevant to the support of laminated mine roof will be a substantial component of this study and initial field work will be conducted in the Sydney Basin.

Qualifications: A PhD degree or equivalent qualification in engineering geology or related discipline together with post graduate experience in this field. Experience in coal mining and/or familiarity with geomechanical mathematical modelling techniques as well as instrumentation techniques would be advantageous

Location: Depending upon circumstances the appointee to this position may be located either at Syndal Vic or at North Ryde, NSW.

POSITION 2—Ref. No. 920/246

Field: Mining engineering.

Duties: To conduct a review of underground mining methods potentially applicable to the Australian coal mining industry Particular attention is to be paid to typical Australian strata conditions such as geology, ground stress, seam and strata deformability and gas conditions Other duties will include participation in the development of physical and mathematical modelling techniques to be applied in the detailed evaluation of selected mining methods An involvement in the development of geomechanical monitoring techniques for use in underground coal mines environments is also anticipated

Qualifications· A PhD degree or equivalent qualification in mining engineering or related discipline with experience of operations in the coal mining industry

Location: Syndal, Victoria

Salary: Appointments will be made within the salary ranges of Research Scientist or Senior Research Scientist. $A14,829-$A21,543 p a Consideration will however be given to appointment at a higher level for outstanding applicants

Tenure: These positions are available initially for 12 months

Applications **in duplicate, stating full personal** and professional details, the names and addresses of at least two professional referees, and **quoting the appropriate reference number(s) should reach**· The Personnel Officer, Australian Scientific Liaison Office, Canberra House, Maltravers Street, LONDON WC2R 3EH, by **18th March 1979.**

Applications in U S A. and Canada should be sent to The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue N W, WASHINGTON D C 20036 9229(A)

FELLOWSHIPS

UNIVERSITY OF WARWICK POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited for a postdoctoral research fellowship in the Departments of Chemistry and Molecular Sciences and Psychology, to work on an M R C sponsored project on specific anosmia and related areas of olfaction. The work will involve a systematic study of olfactory responses to urinous and musk odorants The project could suit either a chemist (biochemist) with an interest in phychophysics or a psychologist familiar with chemical methods.

The post is for two years, beginning as soon as possible, initial salary will be in the range £3,883 to £4,382 per annum on the Research range IA scale.

Applications, enclosing a curriculum vitae, details of research experience and the names of two referees should be sent to the Academic Registrar, University of Warwick, Coventry CV4 7AL as soon as possible Please quote Ref. No: 23/A/79. 9176(E)

QUEEN'S UNIVERSITY
Kingston, Ontario, Canada

Applications are invited for a postdoctoral fellowship to study the genetics and replication of insect baculoviruses The position is supported by M R C Canada for up to two years from receipt of a Ph D degree Stipend for the first year is $11,600 The position is available from April 15, 1979 The desirable qualifications are a background in virology and biochemistry of nucleic acids and proteins.

Please address inquiries to Dr Peter Faulkner, Department of Microbiology and Immunology, Queen's University, Kingston, Ontario, K7L 3N6, Canada 9169(E)

The School of Pharmacy UNIVERSITY OF LONDON

TEACHING FELLOWSHIP IN PHARMACOLOGY

Applications are invited for this appointment at or about September 1, 1979, from suitably qualified persons

For the Teaching Fellowship, which is of limited term, postgraduate experience should relate to the research interests of the Department but additional experience in neuroanatomical, radio immunoassay and receptor binding assay techniques would be very welcome

Normal non-clinical university academic terms of appointment and salary scale Further information can be obtained from Professor D W Straughan

Applications to be submitted by February 9, 1979, in the form of letter accompanied by a C V and the names of two referees to:

The Personnel Officer,
The School of Pharmacy,
29/39 Brunswick Square,
London WC1N 1AX. 9201(E)

NEW ZEALAND UNIVERSITY OF CANTERBURY
Christchurch

AUSTRALIAN NATIONA UNIVERSITY

RESEARCH SCHOOL OF CHEMISTRY

PROFESSORIAL FELLOWSHIP IN ORGANOMETALLIC CHEMISTRY

Applications are invited for app
ment as Professorial Fellow in
area of Organometallic Chemistry

Founded in 1967, the Rese
School of Chemistry is an Integr
School without departments A
fessorial fellow can devote almost
whole effort to research, being
pected only to attend to m
administration in the School and
play some part in University aff
The School has no responsibility
undergraduate teaching It carries
research and teaches graduate stud
is well equipped by modern stand
and is well supported by technical
administrative staff The present D
of the School is Professor D P C
F A.A, F R.S

The School has a total acad
staff of seventy-one, of whom four
hold tenured appointments There
three professors (Professors A.
Birch, D P Craig and A M S
son) and two professorial fellows
J Ferguson and Mr R W Ricka
Professor B G Hyde of the Un
sity of Western Australia has rec
accepted a Chair of Chemistry in
area of Inorganic Chemistry

In the inorganic area there are t
tenured staff members leading i
pendent research groups (Prof
A. M Sargeson, Dr M A Ben
and Dr G B Robertson) They
supported by research fellows
Ph D students It is expected
Professor Hyde will take up
appointment early in 1979 and
an appointment will be made soo
the recently advertised fellows
senior fellowship in inorg
chemistry

The salary is $A29,532 per an
Current exchange rates $A1 e
58p $US1 14

Superannuation benefits are a
able The University meets reaso
travel and removal expenses for
appointee and his family Assi
with housing is provided for
appointee from outside Canberra.
The University reserves the righ
to make an appointment or to
an appointment by invitation at
time.

Further information about
position should be obtained from
Association of Commonwealth Un
sities (Appts), 36 Gordon Sq
London WC1H 0PF.

Applications close on *March*
1979. 9180

FELLOWSHIPS continued

THE UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF ANATOMY
POSTDOCTORAL RESEARCH FELLOWSHIP

A postdoctoral biochemist is re-uired to join a multi-disciplinary am studying aspects of growth and ifferentiation. The successful candi-ate will be responsible for a new I.R.C.-funded project involving the se of monoclonal antisera to study rotein polymorphism in muscle. echnical support will be available. he post is for three years beginning s soon as possible. Maximum starting alary will be £3,883 (plus superannua-on) on the Research Fellow 1A scale.

Applications (three copies), enclos-g a curriculum vitae, details of search experience and the names of ree referees, should be sent to the ssistant Registrar, Faculty of Medi-ine, University of Birmingham, irmingham B15 2TJ, from whom urther information may be obtained. losing date February 16, 1979. Please uote reference RF/ANT/478.

9221(E)

A RESEARCH FELLOWSHIP

tenable for a period of up to three years, is available for work on the regulation of eukaryotic genes by steroid hormones. Emphasis will be given on the isolation, cloning and characterisation of specific genes. Candidate should be experienced in the techniques of nucleic acid biochemistry. Applications (with curriculum vitae) should be sent to Dr J.-P. Jost, Friedrich Miescher-Institut, P.O. Box 273, CH-4002 Basel, Switzerland.

9227(E)

UNIVERSITY OF KENT AT CANTERBURY
BIOLOGICAL LABORATORY
PROTOZOOLOGY GROUP
Applications are invited for a
POSTDOCTORAL RESEARCH FELLOWSHIP

work on the biochemistry of rimidine biosynthesis in *Trypano-na cruzi*. Preference will be given candidates with experience in zymology. Training in protozoo-gical techniques will be provided.

Salary range £3,883 to £4,882. The pointment is financed by the World ealth Organisation's Special Pro-amme for Research and Training on opical Diseases and will be for one ar initially, with good prospects of tension for a further period of two ars.

Application forms and particulars ay be obtained from the Senior ssistant Registrar, Faculty of Natural iences, Chemical Laboratory, The iversity, Canterbury, Kent, to whom mpleted applications should be sub-tted by February 7, 1979. Please ote Ref: A1/79. 9230(E)

STUDENTSHIPS

NIVERSITY OF LEICESTER
DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a A.S.E. research studentship to work the control of aerobic energy con-vation in bacteria during growth in ntinuous culture. The project will supervised by Dr C. W. Jones niversity of Leicester) and Dr J. nton (Shell Research Ltd, Sitting-urne). The studentship is tenable m October 1979 and the successful ndidate will be expected to read for higher degree. Applicants should ssess, or expect to obtain, a good nours degree in Biochemistry or crobiology and should write to Dr W. Jones, Department of Bio-emistry, University of Leicester, icester LE1 7RH enclosing a cur-ulum vitae and the names of two erees. 9101(F)

COURSES

UNIVERSITY OF ABERDEEN
M.Sc. IMMUNOBIOLOGY COURSE 1979-80

Intending applicants for this 12 month course should apply for further details and application forms to Dr J. B. Solomon, Immunology Unit, Department of Bacteriology, University of Aberdeen, Aberdeen AB9 2ZD, as soon as possible. 9190(D)

ASSOCIATESHIPS

HERIOT-WATT UNIVERSITY
DEPARTMENT OF PHYSICS
POSTDOCTORAL RESEARCH ASSOCIATESHIP IN SOLID STATE THEORY

Applications are invited for an S.R.C. Postdoctoral Research Associateship, for studies of Anderson localisation and other topics in the theory of disordered solids, in association with Dr D. Weaire. The starting date should be no later than October 1, 1979.

Informal enquiries can be addressed to Dr Weaire.

Initial salary will be in the range £3,883 to £4,382 per annum (under review) of Range 1A.

Application forms are obtainable from the Staff Officer, Heriot-Watt University, Chambers Street, Edinburgh EH1 1HX. Ref. No. 22/78.

9196(O)

SCHOLARSHIPS

WELSH NATIONAL SCHOOL OF MEDICINE
(University of Wales)
DEPARTMENT OF TRAUMATIC AND ORTHOPAEDIC SURGERY
Applications are invited for a
RESEARCH SCHOLARSHIP

tenable for up to three years from February 1, 1979, in the above Department at the Cardiff Royal Infirmary.

The project involves studies of the bone morphology and morphometry in some common fractures and in human osteoarthritis. The work, which will be done in the Orthopaedic Research Laboratories, will be closely integrated with the use of modern techniques such as microradiography and bone auto-fluorescence, as well as recently-developed special staining techniques. Studies of experimental material might also be involved.

Applicants should hold, or expect to obtain in 1979, a good Honours degree in basic science and be keen to work in the biomedical field and interested in the morphology of hard tissues. An ability to do some simple microscopical observations or some experience with the basic histological techniques would be an advantage. On the other hand, this Scholarship would give the applicant a good foundation for independent studies in the morphology of bone tissue. The appointee to be registered for a Higher Degree with the University of Wales, if suitably qualified.

Conditions are those pertaining to Tenovus Scholarships. Applications, which should take the form of a curriculum vitae with the names and addresses of two referees, should be submitted to Mr Z. Ralis, Senior Lecturer, Department of Traumatic and Orthopaedic Surgery, Cardiff Royal Infirmary, Newport Road, Cardiff, quoting Ref. No. T27/3/9. 9175(H)

SYMPOSIA

CALL FOR PAPERS
EUTROPHICATION IN ESTUARIES

An international symposium on

The Effects of Nutrient Enrichment in Estuaries

will be held on May 29, 30 and 31, 1979, in Williamsburg, Va. The conference is being organised by the Chesapeake Research Consortium and sponsored by the U.S. Environmental Protection Agency. One to two page abstracts for papers on relevant topics should be submitted by February 15, 1979, to:

Dr Bruce J. Neilson,
Virginia Institute of Marine Science,
Gloucester Point, VA 23062.
Phone: 804-642-2111.

9172(M)

LEUKAEMIA RESEARCH FUND
International Research Symposium on
PHILADELPHIA CHROMOSOME POSITIVE LEUKAEMIAS

will be held at the Royal College of Physicians, London, on **Tuesday, April 10, 1979.** Registration fee (includes lunch) £6. Apply for details and registration form to:

Leukaemia Research Fund,
43 Great Ormond Street,
London WC1N 3JJ
Tel: 01-405 0101

How Britain runs its science

This highly successful chart, which appeared in Nature 28 August 1975 (but is still much requested and much referred to), has now been completely revised and updated to include all major changes in the personnel and administration of British science.

Measuring approximately 2' x 3' and containing black-and-white illustrations of prominent figures, copies of this chart are now available at 75p (UK), US $1.50 (Rest of World).

Payment may be made in any currency at the prevailing exchange rate. Cheques should be made payable to Macmillan Journals Ltd. Prices include postage and packing.

To order please complete the coupon below, or write, enclosing the correct remittance

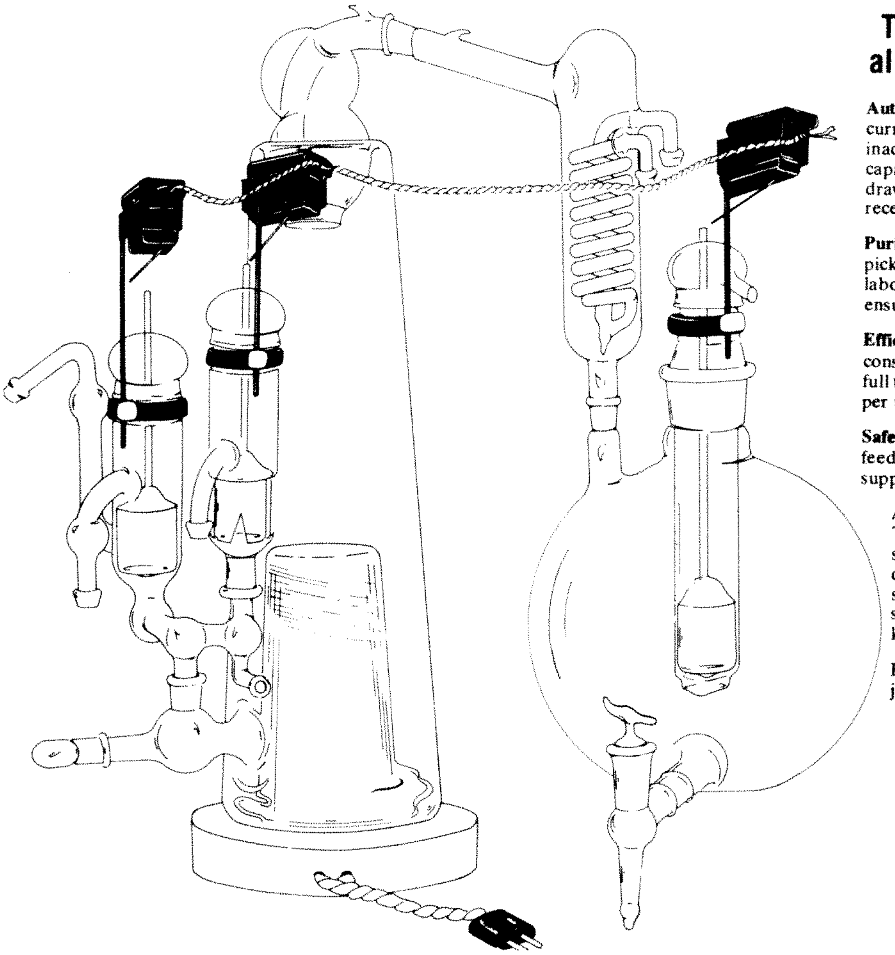
LEADING UK MANUFACTURERS OF



The SCORAH Automatic Electric all glass WATER STILL (patented)

Automatic Can be left on without attention. Heater current cuts off if water supply is interrupted, or inadequate or forgotten. When receiver (5 litres capacity) is full, current cuts off. When distilled water is drawn from receiver, the still resumes operation until receiver is refilled.

Purity Electrostatically charged condenser droplets can pick up fumes, dust and air-borne organisms from the laboratory atmosphere. The design of the receiver vessel ensures absence of such contamination.

Efficiency Heater of Scorah design and manufacture, consumption 1,700 watts, output 2.4 litres per hour (the full theoretical yield). Cost less than 2p per gallon at ½p per unit.

Safety The heating element is out of contact with the feed water, thus eliminating danger from "live" water supply or electrolytic effects of "burn out".

Assembly No retort stands of clamps are required. The 2½-in. diameter ball joint gives a stainless set-up. Outlet cap on boiler for quick periodical drain-off of sediment. The still may be installed on a shelf or platform about 1 ft. above bench level near a sink and enclosed in a transparent plastic cover to keep out dust.

Heat-resisting glass. Interchangeable ground glass joints.

Circle No. 21 on Reader Enquiry Card.

poly-vessels

These expanded polystyrene vessels are used in laboratories and industry for carrying liquid Nitrogen and Dry-Ice. The P.97 size can be used for carrying 'Winchester' bottles of chemicals safely. Supplied with or without carrying handles and lids.

Circle No. 02 on Reader Enquiry Card.

Liquid Scintillation Counting: A Commitment

22 JUN 1979

As the leading manufacturer of radiochemicals, NEN has come to know a good deal about the problems you face in liquid scintillation counting. So much so that in the last ten years we have developed the industry's most complete line of liquid scintillation chemicals, with over 30 products stocked worldwide. They include our AQUASOL® Cocktails – the world's most referenced scintillators, and BIOFLUOR™ – the highest efficiency product for aqueous tritium counting.

Our commitment goes beyond making products. We provide worldwide LSC technica expertise through field rep resentatives trained to assist you i the selection of scintillation chemical tailored to your needs. And they'r supported by the industry's onl LSC Applications Laborator Write for complete informatio

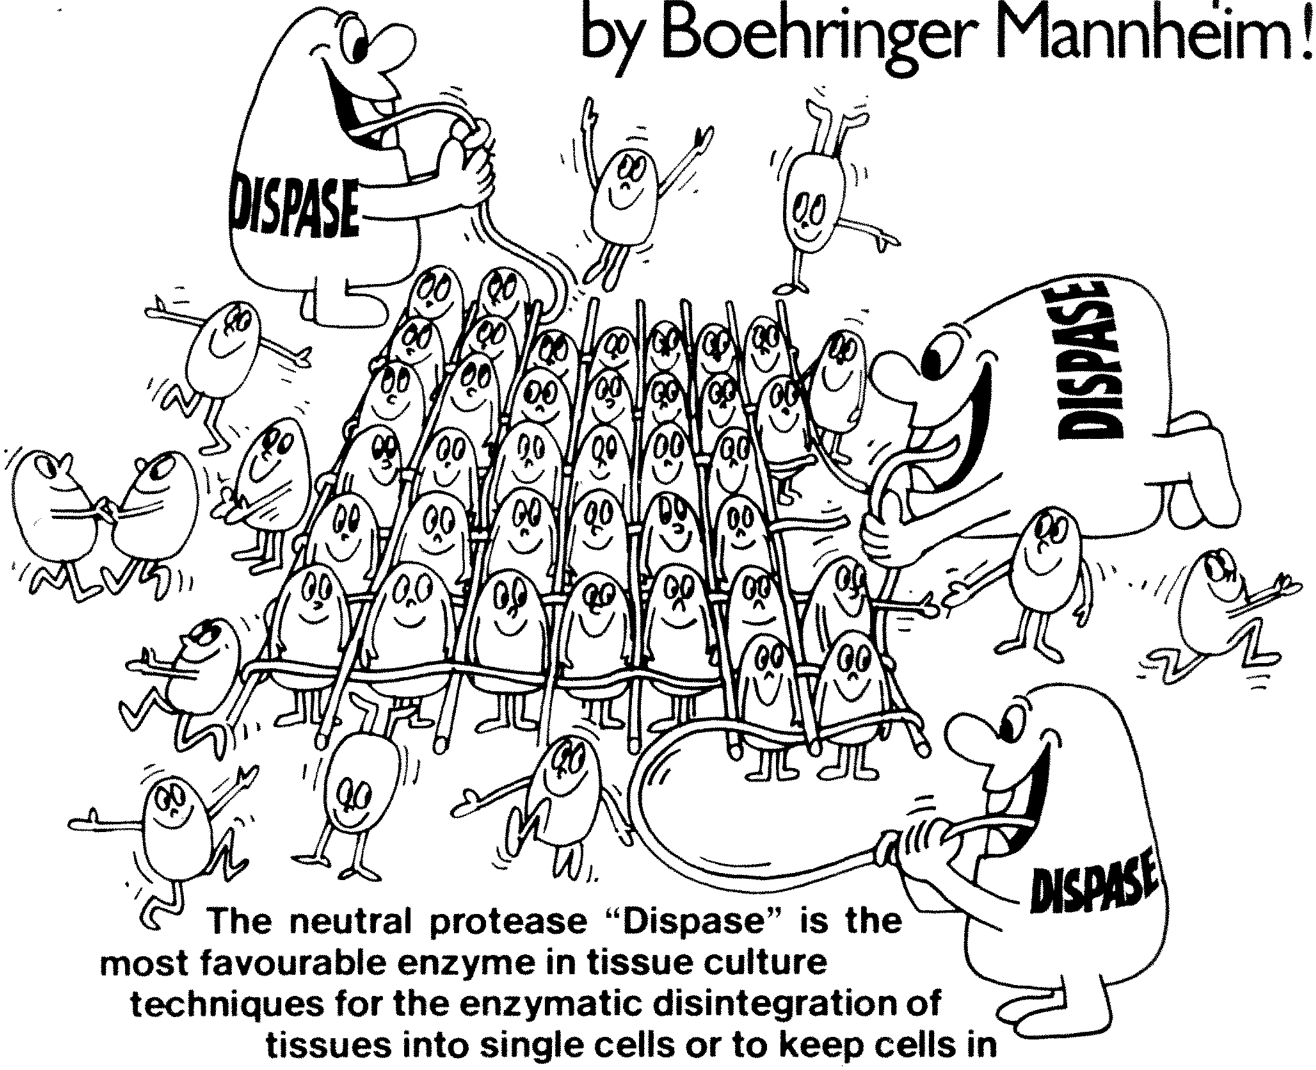
The big liberator is here!

A revolution in tissue culture techniques by Boehringer Mannheim!



The neutral protease "Dispase" is the most favourable enzyme in tissue culture techniques for the enzymatic disintegration of tissues into single cells or to keep cells in suspension culture.

The advantages over trypsin are:

- * no damage of cell membranes
- * no inhibition of cell growth
- * tissue disintegration in presence of a complete nutrient medium even with serum
- * increase of the yield of living cells
- * no loss in enzyme activity under tissue culture conditions
- * no contamination by viruses or mycoplasms possible

Commercially available: Dispase, Grade I, Cat. No. 241 750
Dispase, Grade II, Cat. No. 165859
Dispase/Collagenase mixture, Cat. No. 269638

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963–65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**, 1 (1975) and **264**, v, 11 Nov. (1976).

When you're studying cyclic nucleotides and you don't know which way to turn

We understand that when you are working in the cyclic nucleotide area, the subject is so diverse and so complex that you don't want to have to worry about the problems of accurate measurement.

So we would like to take a little weight off your mind and offer you our two kits in this field.

Cyclic AMP and Cyclic GMP.

Both of the tests are simple, accurate and will take you about four hours from start to finish.

So it's not surprising that you can carry on with your research and leave the problems of accurate measurement to us.

You know where you are with our Cyclic AMP & GMP kits

Converting intelligence into wisdom

DOES Britain use its intellectual resources wisely? There can be little doubt that the British education system has proved itself competent in the past at identifying and nourishing the high flier, from primary school through to university. Even in this time of egalitarianism there still seems a recognition of the need to sustain the outstanding student who may contribute something of exceptional value to society in the future. Twenty years of education can turn out people whose intellectual skills have been polished and sharpened to a high degree. But do we provide the right environment, as a nation, to capitalise for the next forty years on these skills; not just for the benefit of an organisation but also so that the individual may continue to feel a sense of fulfilment from being intellectually extended?

There is a trivial sense in which every educational system is immensely wasteful, and must be so to be effective. The vast majority of what is learnt in school or university is never specifically going to be used later in life but can only at best be described as intellectual compost—material which helps to explain 'the way things are' and which may illuminate future thinking in an undefinable way. But there is a far less trivial, and far more nation-specific way in which intellectual resources may be used or squandered. If the structure of a society is so heavily compartmentalised that the only way ahead is to become a specialist, and progressively to acquire greater expertise in a narrower discipline, then there is a small chance that intelligence will lead to wisdom. If there is an element of cross-movement open, at all levels, there is at least the possibility that every year will bring sounder judgement and more job-satisfaction.

Britain is indubitably a compartmentalised society: civil servants, academics, lawyers, doctors, politicians, industrialists and many others—they all pursue their own separate and highly specialised paths, defending themselves against outsiders and looking askance on those few who choose to step off a well-defined ladder.

The civil service is as good, or bad, an example as any. Competition for entry into the service is fierce; very intelligent people enter the service in their twenties. Whatever the label they carry—administrative, scientific and so on—they can be reasonably sure of a lifetime of employment, and indeed very few ever think of changing career. Certainly during that lifetime for many there will be varied work to do, but it will all be within the framework of serving the state. Even within this, the largest compartment of them all, there are any number of sub-compartments. A scientist who, at the age of 40, feels he has run out of steam is not going to find the administrative or executive branches waiting with open arms for him, regardless of the undoubted variety of experience he might bring to a new job. Not, it must be admitted, that civil servants show all that much interest in changing their environment; a recent scheme to encourage temporary moves between the service and industry and academe, after two or three years of very modest success, is now in abeyance.

Because the civil service has built up great bodies of specialist expertise (some excellent, some not) within its walls, it feels relatively little need to share its problems with others or to draw in the outsider for a period to give a new perspective. This then leaves academics, for instance, ill-informed on many questions of broad national or international interest and inclined to withdraw even further into their laboratories, common rooms and learned societies. Not of course, that academics can be depicted as entirely innocent of their own compartmentalisations, both to keep the outside world at bay and to maintain fine distinctions between disciplines.

The end result of all this is by no means that Britain lacks experts in almost every subject under the sun, but that broader perception is often lacking. And surely scientists, as well as anyone, know how important a multidisciplinary approach is in the advancement of knowledge and understanding.

Of course, mobility must not be preached for its own sake. There are many who are at their happiest and most productive when pursuing their own specialisation, and these would profit little, and be much irritated by an ethos in which they were viewed with suspicion for sticking to what they do most effectively. On the other hand there are equally many who would profit greatly from the chance to diversify their career.

No single grand gesture will shake Britain out of its present over-specialised character. Rather a variety of smaller things have to be done: attitudes must change, terms of employment must be revised, even the penalty that the mobile suffer in their pension must be looked at. And there certainly ought to be more serious discussions about developing new institutions which could effectively span the public and private sector, looking at major policy problems but from an outsider's point of view. □

US boosts basic science, but overall R & D drops

Defence, energy and space head for large increases in basic research funding in President Carter's 1980 budget.

David Dickson reports

"The budget for fiscal year 1980 is lean and austere". The words that President Carter chose to open his budget message to Congress on Monday apply directly to proposed funding levels for research and development—but in a time of financial conservatism basic science has done relatively well, being scheduled for a real growth of 20% above the expected level of inflation.

The overall size of the R&D budget reflects the President's choice of reduced public spending as a major weapon to fight inflation. Thus total R & D obligations are planned to rise only 4.1% to $30.6 billion, the smallest increase in the R & D budget since the Nixon era.

Given this general constraint, the main issue that has occupied government agencies in preparing their budget requests has been to decide how the money should be distributed along the R & D spectrum And it seems to have been generally accepted that optimal long-term results can be achieved by shifting support for 'development' projects back to the basic research end (a trend initiated last year, though dealt with unsympathetically by Congress).

The net result of this is a projected increase of 9% in the funds available for the support of basic science, about 2% above the expected level of inflation, with increases of twice this amount for some agencies, such as the departments of energy and defence.

Those projects to have suffered are the ones which the administration feels have reached a stage at which they could be taken up in other ways—if at all. There will, for example, be a reduction in support for coal conversion technologies and hydroelectric and solar heating R & D, although more money for basic research in solar energy.

One agency to have done well in the budget review is the Department of Defense, which accounts for about 45% of federal support for R & D The department is scheduled to receive an increase of 7% in its total R & D funds to $13.8 billion, and within this an increase in basic research of 17% from $373 to $436 million.

The department's research money, whose growth reflects a general growth in defence spending that characterises the whole budget, will be used to support projects such as the MX intercontinental ballistic missile and new research on very high speed integrated circuits. There will also be more defence money spent in university research departments.

An even greater increase—18.8%—is scheduled for basic research supported by the National Aeronautics and Space Administration. However, here the figure is slightly deceptive, since much of this will be required to

Space scientists disappointed: The budget for the National Aeronautics and Space Administration does not contain any major new mission starts. It comes as a disappointment to space scientists, who had hoped that at least some of their proposals might have escaped the cuts. Top of the list of projects which will not receive funding are plans to send an orbiting imaging radar to Venus—particularly important in view of the failure of some of the equipment on board the current Pioneer missions—and plans for a gamma ray observatory.

Other casualties include a national oceangraphic satellite system, and plans to place a block order for a number of multi-mission satellites (mms). These will now be ordered individually, which could increase the costs of proposed British mms. Although these and other new projects were included in a $4 9 billion request which NASA put to the Office of Management and Budget, they were all discounted to ensure that general budget constraints and increased shuttle costs did not cut into existing programmes.

10% more for university research: The total federal R&D outlays to universities and colleges is planned to increase by 10% in 1980, considerably above the overall increase in R&D funding. The largest increase will be in research funds from the Department of Defense, scheduled to grow on campuses by 13% to a total of $359 million. Other major increases are planned for DHEW (11.9%) and the National Science Foundation (12.1%). In the proposed budget for the National Institutes of Health, funds for research projects awarded on a competitive basis are planned to fall from $494 million to $279 million, while non-competitive funds are scheduled to increase by approximately the same amount.

Boost for nuclear physics: After several years of relative neglect, there is some good news for nuclear physics, and government officials say that the increased support should continue "for some years to come". Funds have been made available in the Department of Energy's budget for a major heavy-ion facility at Michigan State University; an energy doubling electron beam recirculator at the Bates Linear Accelerator of the Massachusetts Institute of Technology; and an experiment staging area at the Anderson Meson Facility of the Los Alamos Scientific Laboratory. The expansion in nuclear physics has been partly made possible by the near completion of the Cornell storage ring, funded by the National Science Foundation. Construction of the Michigan facility is to be transferred from the NSF to the Department of Energy, although the foundation will continue to cover research costs.

Research on environmental hazards: As a reflection of the growing importance of scientific findings in the control and regulations of environmental hazards, the administration is proposing to make a major increase in the research budget of the Environmental Protection Agency. Obligations for R&D will increase from $400 million to $436 million, with a 16% increase in longer term research.

NSF instrumentation grants up 50%: The National Science Foundation is planning a 50% increase in its allocation of funds for research instrumentation and equipment, a source of growing concern in recent years and one of the areas in which universities and research institutions have been hit hardest by inflation. Announcing this increase, NSF director Dr Richard C. Atkinson said: "There is no question that we have been lagging behind in equipping our laboratories". In many Western European countries, the proportion of the research budget devoted to instrumentation was almost three times as high as in the US. The increase will raise the funds for instrumentation from $54.4 million in the current fiscal year to $81 6 million. The extra money is contained in a 12.4% increase in NSF funds for research in physiology and cellular and molecular biology, and a 15.4% increase for environmental biology.

0028-0836/79/0277—0252$01.00

Carter: fighting inflation with spending cuts

support projects that have already been initiated—such as the Jupiter Galileo mission—but are now moving into an expensive phase.

Another burden on NASA's budget is the increased costs of the Space Shuttle, for which the agency is already having to approach Congress for an extra $185 million as a result of delays caused by engine test failures. The net result is that although there will be a 20% increase in NASA's support for space science and applications, there is no provision for any new programmes.

At the Department of Energy, which is having to bear much of the cutback in federal spending, there is said to have been considerable dispute over which end of the R & D spectrum should bear the brunt of the cuts. In the end demonstration projects were the ones to suffer. Within an overall R & D budget that will remain virtually constant in 1980 at $4.6 billion, there will be a 17% increase in support for basic science, sufficient to ensure continued support of high energy physics at current levels, as well as a boost for nuclear physics and solar energy research.

As far as the National Science Foundation is concerned, the administration has asked for a relatively modest overall increase in funding of 8.4%, bringing the agency's budget to $11.006 billion. Basic research is scheduled for an 11.8% increase, with large increases in chemistry, the earth sciences and environmental biology, and particular emphasis on upgrading equipment. Unlike previous years, no great increase is suggested for NSF's applied science activities. The budget for "problem-focused research applications" is to fall by 11.6%.

Projected figures for the Department of Health, Education and Welfare are a somewhat unreliable guide to what will actually be spent, since traditionally they are raised substantially by Congress. With this in mind, the administration has requested a budget for the National Institutes of Health of $1.4 billion, less than 1% higher than the current year.

Commenting on the overall budget figures, Dr Frank Press, Director of the Office of Science and Technology, said that "in general we feel that R & D has received good treatment. And when you add the basic research initiatives, we feel this is a very strong research budget."

Dr Press said that President Carter's initiative in increasing funds for basic research had become a model for other countries spurring similar increases, for example, in France, Britain, and West Germany. "It is nice to see that the US research dollar has leverage of this kind", Dr Press said. ☐

Sun shines on solar energy: Research on solar energy, a proposed cut in which last year brought a storm of protest from the environmental movement, is planned to receive an increase in funding of 24%. Longer term solar-related technology development and applied research will grow by 40% in 1980. In particular, the Department of Energy's budget request includes funds for the construction of a new 300-acre research facility at the Solar Energy Research Institute in Golden, Colorado.

Administration tries again on competitive agricultural research grants: The US Department of Agriculture is once more proposing a major increase in funding for competitive research grants, a proposal which has come under heavy fire in Congress for the last two years, during which such increase have been considerably cut back. In its proposed 1980 budget, the President has asked for a total of $30 million, two-thirds of this for basic research on the efficiency of food production, and the rest for the improvement of human nutrition. One major initiative in agricultural research is a major inter-agency effort to assess the value of space remote sensing data in obtaining early estimates of the effect of natural disasters on crop conditions, and improving world-wide agricultural production forecasting. Total funding for these projects, which will involve the departments of Agriculture, Commerce and Interior, as well as NASA and AID, is estimated to increase from $18 million in 1979 to $29 million in 1980.

No funds for Clinch River or nuclear reprocessing: The Administration is sticking to its previous position on two hot political issues in the nuclear field by requesting no funds for either continuation of the liquid metal fast breeder reactor at Clinch River in Tennessee or for nuclear fuel reprocessing. Although $504 million is being requested for LMFBR research and development, indicating a continued commitment to the fast breeder, the administration repeats its position that the proposed Clinch River demonstration project "is both premature and uneconomical".

Research on nuclear fuel reprocessing is proposed for termination in 1980, in line with President Carter's non-proliferation policy. In its place, emphasis will be placed on "once through" nuclear fuel cycle that will be used in conjunction with improved and more efficient light water nuclear power plants. Research funds for the Department of Energy provide additional support for the examination of alternative geological sites for a deep nuclear waste depository, and for developing new waste forms that could be used for the disposal of high level defense wastes. President Carter has also announced that he plans to introduce a "spent nuclear fuel Act" which will authorise the department to accept spent nuclear fuel for storage and disposal in return for a one-time charge.

Major effort in microelectronics: Three federal agencies—the Department of Defense, the National Science Foundation, and the National Bureau of Standards—are proposing to carry out complementary efforts in the field of microelectronics and submicron science and technology in 1980, involving a total budget of $41 million. At the NSF, efforts will be concentrated on fundamental research into the properties of microstructures, aimed at supporting a number of applications in electronics. The foundation will also provide training for scientists in this field, where a shortage of graduates is claimed by some to be holding back the efforts of private industry. The Defense Department is planning a major expansion of its research into very high speed integrated circuits, despite a major split in the defence industry over whether or not the technology already exists to meet the department's needs.

President halts child research building: Permission to construct a $37 million child health research facility at the National Institutes of Health has been withdrawn. It was considered low priority in a time of budget stringencies.

New US agency to focus research aspect of development aid

David Dickson reports from Washington on President Carter's proposal for a foundation for International Technological Cooperation

One of the relatively few new initiatives in the budget recommendations submitted by President Carter to the US Congress last Monday was the proposal to establish, under the foreign aid appropriations, a Foundation for International Technological Cooperation (FITC).

The foundation is intended to act as the focus for the research and development component of the US development assistance effort. It is presently being conceived as one element in a proposed international development cooperation administration, which would also include existing bodies such as the peace corps and the Agency for International Development (AID).

Funding for the FITC would be about $100 million for the first year of full operation, beginning 1 October 1979, although only a relatively small amount of this—about $25 million—would be new money, the majority of support resulting from the transfer of research projects currently carried out by AID. Eventually it is hoped that the foundations will have an annual budget of three to four hundred million dollars, the same order of magnitude as the National Science Foundation.

Plans for the foundation already figure prominently in the US national paper for the United Nations Conference on Science and Technology for Development (UNCSTD). However, criticisms of various aspects, such as the degree of autonomy which FITC will—or should—be able to exercise from existing aid programmes, and from overt US interests, indicate that the administration may face an uphill task in getting its plans accepted.

The proposed foundation was announced last March in a speech by President Carter in Caracas, Venezuela. It is largely the brain child of Dr Frank Press, director for the President's Office of science and technology policy, and reflects the same type of approach to R&D planning that he has injected into areas of domestic policy.

A planning office, reporting directly both to Dr Press and to Mr John G. Gilligan, administrator of AID, was established last summer. It is directed by Dr Ralph Schmuckler, previously dean of international studies and programmes at Michigan State University, and chairman of AID's research advisory board.

According to Dr Schmuckler, the foundation will have two main objectives, first, to help strengthen the scientific and technical problem-solving capacities of developing nations; and second to focus attention of US scientific resources on problems of concern to developing countries.

Although precise details are yet to be worked out, FITC is expected to operate by identifying various "problem-areas"—in contrast to the country-by-country programming of bilateral aid programmes—and then to work out which are the crucial problems in these areas.

"The programming process will be a bit like a funnel. At the top we will have all types of state-of-the-art analyses, with participation by agencies already involved, by developing country representatives, and by scientists. We would then move from a broad sweep to an increasingly narrow focus on particularly important goals that could be realised over a period of five to ten years", Dr Schmuckler said.

To illustrate the type of research that might result from this process, he cites work being supported by AID on the possible production of a vaccine against malaria, "A good example of an analysed, research problem dealt with initially in a very low-cost way, but resulting in some scientific breakthroughs that offer the possibility of a solution to a major health problem".

Besides research itself, however, an equally important part of the foundation's activities will involve helping to build research infrastructures in developing countries—for example by assisting in the training of scientists and technologists through courses and seminars, and occasionally providing short-term financial support for local research initiatives.

Above: protection against malaria. The disease disables 30–40% of the working population where the disease is rife. Research into a vaccine is "a good example" of the work FITC might undertake.

"We aim to spend the majority of our money in the developing countries themselves—a rough estimate is 75%", says Dr Schmuckler. "The rest will go to US universities and research institutions, but only to support work which is directly tied to activities overseas".

And to ensure what he calls a "real live audience" for the foundation's efforts, roughly one-third of FITC's advisory council—which will be responsible for recommending areas for study to the foundation's director—will come from developing countries.

Legislation to set up the foundation is soon to be presented to Congress as part of an amendment to existing foreign aid legislation. However, there are already signs that various criticisms of the current plan could lead to a tough political battle.

One criticism, for example, is that the foundation will be so closely linked to existing agencies such as AID that it will not have sufficient autonomy to apply an objective analysis to third world research needs (although others point out that it may be necessary to emphasise US interests to get the FITC accepted by Congress).

"The basic ideas is a very good one—but I am not very happy about the way that things are working out, particularly since the foundation seems to be becoming a subsidiary of AID almost as soon as it is born", says Professor Michael J. Moravscik, professor of physics at the University of Oregon, and an active member of the recently-formed Council on Science and Technology for Development.

Professor Moravscik and others are now putting their support behind an alternative proposal suggested by Senator Adlai Stevenson for a foundation for international scientific and technological cooperation, an agency similar in concept to the FITC, but having the power of autonomy enjoyed by the National Science Foundation.

A bill proposing such a FISTC is to be introduced into Congress by Senator Stevenson within the next few weeks. Attractive as the greater autonomy may be to some, however, its chances of success against the administration's FITC proposal, in a Congress increasingly concerned about public accountability for the use of federal funds, remains uncertain. □

Cadmium puts UK village at risk

Cadmium, a light metal mined with with zinc, has been discovered in abnormally high amounts in stream sediment in the village of Shipham, the site of a zinc mine abandoned two hundred years ago. The Department of the Environment (DOE) has warned the villagers not to eat local produce and not to smoke and has initiated a £70,000 investigation to study the effects on health.

Levels of cadmium found in the soil varied from 11 ppm to 998 ppm. The accepted safe level is less than 1 ppm. Serious cadmium poisoning occurred in Japan from 1962 to 1968 caused by levels of cadmium in rice paddies of 1–50 ppm although there were other contributing factors in Japan that are not present in Shipham—such as dissolved cadmium in water.

Shipham water has been tested and is "absolutely safe" said Mr Denis Howell (a minister in the Department of Environment). "There is cause for concern but not for alarm. It is in nobody's interest to exaggerate the alarm" said Howell. Local residents have known for years that vegetables grow yellow in certain locations, and there is a local ailment—called "Shipham tummy"—which could be a sign of chronic cadmium exposure. Long term effects are poorly known but symptoms of cadmium poisoning are diarrhoea, vomiting, stomach pains and choking.

The high concentrations were discovered in the course of an Imperial College geochemical reconnaissance of England and Wales begun in 1967. The study took 50,000 stream sediments from tributary drainage over the whole country during a ten week period in 1969. A complementary sampling of soil and rock was undertaken in Shipham to test for the presence of elements in areas of poor drainage. The high cadmium count found in this survey was followed up by sampling garden soil in conjunction with researchers from the Westminster Hospital Medical School in Spring 1978. These results were released to the DOE last August.

Dr Ian Thornton, Geochemistry Department at Imperial College and participant in the original study says that Shipham is probably unique. Calamine, $ZnCO_3$, was mined in Shipham whereas in other mines it was galena, zinc sulphide.

Joe Schwartz

Biochemist challenges redundancy

An industrial tribunal currently underway in Manchester raises new questions on the power of granting agencies to make scientists redundant. Dr David Pillinger, FRIC, 39, a biochemist employed at the Christie Hospital in Withington near Manchester, is the first senior staff member of the National Health Service to be made redundant since 1948. Pillinger's case, brought to the tribunal with the aid of ASTMS, squarely confronts a complicated legal issue affecting thousands of scientific workers in the UK; who is their employer ? Is it the agency that provides the money or the institution that does the hiring?

Pillinger was hired in 1962 by the Manchester Area Health Authority to do cancer research at the Christie Hospital. At that time there was no special category for research workers and Pillinger was engaged on the same basis as the clinical biochemists and physicists, with a permanent NHS contract, the funding coming from the British Empire Cancer Campaign In this arrangement the Health Authority provides a permanent contract even though it does not provide the funds, with the understanding that the contract will be underwritten by the Authority should outside money dry up.

In 1972, Professor L. G. Lajtha, Director of Research in the Christie Hospital's Patterson Laboratory, attempted to bring all research workers under MRC short term contracts of three to five year duration. Pillinger refused to sign such a contract but eventually was persuaded in 1973 to take a post of unlimited duration on a block grant, a form of funding that covers several different projects. This was a hybrid contract in which the employer was still the Health Authority but the money and pay scales were set by the MRC. Says Pillinger, "There is no doubt, nor has it ever been questioned, that my employer is the Area Health Authority."

Nevertheless in June 1978, Pillinger was told by Lajtha that he was to be made redundant. In a letter from the MRC Lajtha was told that there was to be no reduction in funding for Pillinger's chemotherapy project but that the MRC did not feel "that Dr Pillinger should continue to be supported even though a senior scientist is needed" Pillinger pressed Lajtha for an explanation and in notes submitted to the tribunal quotes Lajtha as saying, "I doubt if we will ever be told, since the MRC is an autonomous body. It does not have to give account to anybody for any of the decisions they take."

The Christie Hospital administration is supporting Pillinger. Mr D. C. Critchley, former Sector Administrator, was called by Pillinger's counsel, Ms Janet Smith, to testify last Monday Lajtha, however, is critical of the hospital administration. Calling Pillinger's case a "purely administrative problem" Lajtha feels that Pillinger's original contract was a case of "administrative irresponsibility" and that the old management should have made it clear that a scientists's employment must depend on the ebb and flow of grant money. Lajtha says that the MRC project grant renewal did not permit him to employ a Senior Grade Scientist but only a Grade 2 Scientist (equivalent to a Lecturer). When asked why he did not make representations on Pillinger's behalf to the MRC Lajtha said that he had already presented the case to the MRC and that they were "fully in the picture".

Behind the official language of dismissal and tribunal, however, lies a story of research conflict and scientific disagreement. In 1969 Pillinger returned from a two year stint at Columbia University in New York where he worked with Ernest Borek on tRNA modification by methylation. Pillinger began work on this line at the Christie Hospital and produced 12 publications in three years. In 1972 this project was terminated by the MRC. Lajtha requested that Pillinger start work on a model of cancer cell proliferation in which tissues were hypothesised to produce proliferation inhibitors Pillinger's job was to isolate the putative inhibitors called chalones. The technique used cell extracts in water and the fraction of MW of around 1000 was observed to inhibit cell division. Pillinger was critical of this work and thinks that the results were artefacts (The cell division assay used radioactive thymidine as a marker and Pillinger felt that the cell extract fraction found to inhibit division probably contains thymidine so that a decrease in thymidine uptake was an artefact of the preparation.) In 1974 Pillinger transferred to other work on cancer chemotherapy with Brian Fox, Head of Experimental Chemotherapy. It was on this project grant that the MRC found that Pillinger's services were no longer necessary.

UN desert unit to concentrate on national projects

DISILLUSION with transnational programmes to halt the growth of the world's deserts is causing the United Nations Environment Programme (UNEP) to turn to specific national projects, the new director of UNEP's desert unit said last week.

The director, Jens Høgel, said that the criticisms of Professor Mohamed Kassas (reported in *Nature* last week, p167) were "a long step ahead" from the original political naïvity of the 1977 United Nations Conference on Desertification (UNCOD), which proposed six giant transnational projects based more on scientific optimism than political reality. Professor Kassas was in fact a major force behind UNCOD.

UNCOD passed the six projects on to UNEP, which then had the task of implementing them. Details of the projects—which include matters such as the management of the massive North East African fossil water aquifer—are still being drawn up, but, says Høgel, "it is better to put our eggs in national baskets".

One such plan is for the establishment of new industries in arid zones to attract populations back on to desert margins. These would bring water with them and help to stabilise desert movement. Nine countries—Afghanistan, Algeria, India, Iraq, Mali, Mexico, Peru, Spain and Tanzania—are submitting project proposals to a meeting which will take place in Moscow from 5–8 February. The USSR will provide the necessary funding.

Nevertheless national progress "is still going a bit too slow". And while many rich northern states "have indicated very clearly that they are interested" in supporting UNEP's desert work, no money will be forthcoming from them until specific projects are agreed.

"But there is no reason for despair" says Høgel. It took 30 years from the recognition of the problems of development around the time of the second world war before effective action began to be possible through the United Nations Development Programme (UNDP) and so on. "We have just recognised desertification (at UNCOD) in October 1977. But it won't take three decades now; we have UNEP, a new will to succeed, and a tremendous pool of international expertise to call on."

Nevertheless there is a great deal of inertia to overcome. The independent Club du Sahel, funded mostly by the US and France, was created in 1975, "but when I left the Sahel four months ago there still wasn't any action".

Høgel is adamant that the UN organisations have not been "sluggish and inefficient" as charged by Professor Kassas. "We are at the top of the scale compared with most bilateral agencies, and what is more you can't lose the United Nation's goodwill." On the other hand, Høgel can see bilateral agencies imperialistically forcing their solutions onto the recipient countries. "This leads to reticence, the resulting institutions won't function, and it will breed ill will. And the recipient countries hold their best people back".

The approach of UN agencies, like UNEP's desert unit for example, is to encourage the individual countries to create their own projects, "so there is no question of imperialism". Furthermore the UN can call on expertise internationally, whereas bilateral agencies are limited to the donor country.

In the Sahel, however, Høgel recognises the enormous resources that the Club du Sahel can call on—some $2,000 million compared with $60 million in UNEP's Sahelian office—"and the beneficiaries are the same". The Sahelian population is the worst hit and also the poorest desertification area in the world.

Høgel: supporter of national projects

The desert unit at UNEP is still very small. UNCOD recommended a professional staff of ten, and some think it should be larger, but so far Høgel has himself and five others. Previously Høgel was a development manager with UNDP in Upper Volta; he is a 46-year-old Dane with wide experience in the third world. To assist him he has a Soviet professor in soil science, a Sudanese ex-vice-minister of agriculture (and a doctor of veterinary medicine), an Afghani programme officer, and a Belgian meteorologist. The latest recruit is a Malian ex-nomad turned sociologist of nomadic populations.

The unit's work covers the six transnational projects, establishing new national projects, organising national courses on the most basic desert management, and map-making. The original UNCOD map has been widely criticised as impractical, on too small a scale, and lacking clear definitions of the desertification process. A new one at 50 to 100 times the scale (1:1 million) is being drawn up by Professor Harold Dregne at Texas Technical University, but it will take two years and is already leading to a lot of disagreement on defining borders. "But the footwork needed to arrive at the map is very important" says Høgel. "At least we ought to know in detail where the danger regions are."

Robert Walgate

"He drinks one, then needs three more to forget about the cancer in the first."

German scientists detect carcinogens in beer

SCIENTISTS at the German Cancer Research Centre in Heidelberg have discovered traces of nitrosamines, one of the strongest known cancer inducing agents, in beers made in Germany, Britain and other European countries.

A two-year study of 158 beers financed by the German government, with support from the US National Cancer Institute, revealed traces of nitrosamines in 70% of the samples. The chemical, which is thought to be produced by contact with nitrous oxide when the beer's malt is dried, was found in much higher levels than in foodstuffs such as pickled meats, ham and sausage also included in the study.

Dark beers and stronger beers contained higher levels of nitrosamines than light beers such as lager and pilsner, according to the head of the research team, Professor Rudolf Preussman.

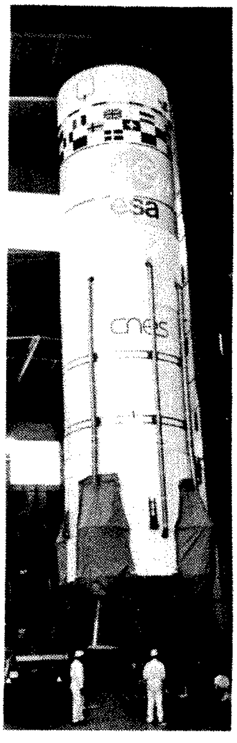
news in brief

British Association meets on UNCSTD: As preparations mount for the UN Conference on Science and Technology for Development (UNCSTD) in August, the British Association for the Advancement of Science is organising a one-day public symposium on March 8 to allow 'non-government bodies' a chance to express their opinions. Seven main speakers will put points of view ranging from that of the UN, from Guy B. Gresford, who is Deputy Secretary General UNCSTD, New York, to the 'trade union view' by Barry Sherman, Director of Research at ASTMS. Sir Ieuan Maddock, who will also chair the meeting, presents 'a British scientist's view', while the multinational companies will be covered by Mrs Doreen Wedderburn of Unilever and chairman of a CBI working group. Professor A. H. Bunting (Reading University) and Adrian Moyes of Oxfam are scheduled to present the reaction of the late-developing countries and the 'very poor' to science and technology; while Professor Robert A. Shaw, who holds the chemistry chair at Birkbeck College, London, will speak on the educational consequences of UNCSTD, in a talk that will undoubtedly range well beyond its title.

The BAAS seems confident that the meeting will be both lively and useful. With this line-up of speakers and the quality of contributions expected from the floor, a forum of this kind should be the best way of putting across the 'unbiased opinions'—in a BAAS phrase—of British scientists to the British UNCSTD delegation. (Further details from the symposium secretary, 01-734 6010 extension 377.)



Accident delays European Space Launcher: Development flights of the European Space Launcher, Ariane, have been delayed five months due to failure of a safety device on 28 November 1978. An ignition delay in the combustion chamber caused an excess of hydrogen to build up which resulted in a "violent ignition", according to ESA. The explosion caused extensive damage to the propulsion system requiring the launcher to be dismantled and refurbished. But initial fears that the stage or propulsion design might have been responsible were unfounded. An inquiry conducted by the project team found that a malfunction of a hydrogen flow monitor was responsible. The new dates for the first four development flights are: early November, 1979; early March, 1980; June, 1980; and October, 1980 (unchanged). The revised schedule permits the first operational flight to go ahead as scheduled in December 1980.

US scientists urge further intensive study of Mars and Venus: Mars, Venus and the Earth should receive the major focus in exploration of the inner solar system for the next decade, according to a report published recently by the National Research Council, the study section of the US National Academy of Sciences. "The comparative planetology of these bodies is a key to understanding of the formation of the earth, its atmosphere and oceans, and the physical and chemical conditions that lead to the origin and evolution of life", the report says, although it adds that the atmosphere-free terrestrial planets, namely Mercury and the Moon, are "complementary bodies of high scientific interest".

As for further missions to Mars and Venus following the Viking missions of 1977 and the current Pioneer missions, the report says that studies should be initiated to develop the special technology needed for the return of samples, as well as *in situ* experiments. In an "overview" section of the report, the committee says it is deeply disturbed by the near-term outlook for the US planetary programme, and that the struggle in 1978 to obtain approval of the Jupiter Orbiter Probe, after a three-year hiatus in planetary mission starts, was a reminder that a national policy for planetary exploration was still to be defined.

The report also says that in view of the lack of direct and substantial information on Soviet plans for planetary exploration, and because of the limited extent of past scientific exchanges, "it appears desirable to establish a much improved vehicle for discussion of US-USSR interests in planetary exploration".

US to assess environmental impact of foreign projects: All US federal agencies must in future prepare an assessment of the likely environmental impact of any new project to be carried out in a foreign country, following an executive order signed last week by President Carter in Washington. Projects that could be affected by the order include the construction of a nuclear reactor in the Philippines, which critics claim to be dangerously near an earthquake fault, and US participation in spraying Mexican marijuana fields with the herbicide paraquat.

The presidential order follows almost a decade of dispute over whether the National Environmental Protection Act of 1969, which requires environmental impact statements on federal projects within the US, was also intended to cover projects carried out overseas. The Council on Environmental Quality has always maintained that this was, indeed, the intention of the US Congress in passing the Act; in contrast, the US State Department has claimed that carrying out such an assessment would be a violation of the sovereign rights of other countries. Dr Charles Warren, chairman of the Council on Environmental Policy said that the order was a response to a growing worldwide concern that governments are undertaking major actions without enough consideration of the consequences.

Libyans deny A-bomb intentions: Libyan officials have denied charges by the US Federation of American Scientists that the country intends to acquire nuclear weapons. According to Mr Ahmed Shehati, head of the foreign affairs office of Libya's ruling People's Congress, Libya has "neither the time nor the potential" to acquire nuclear weapons itself, although it believes that the superpowers should curb any further transfers of nuclear-weapons technology to Israel, South Africa or Rhodesia. The charges were made after a trip to Libya two months ago by FAS secretary Dr Jeremy Stone.

Birmingham University challenges smallpox trial: Birmingham University has won leave to apply to the High Court to quash its prosecution over the smallpox case. The university claims the trial has been prejudiced by the premature release of the Shooter report on the incident.

No crisis, but save energy, say Soviets

Vera Rich reports on Soviet energy in a year when nuclear generating capacity in the USSR is to increase by 50%.

DURING the past year, Soviet energy planners have issued a number of highlevel denials of anything approaching an energy crisis. Since the publication of the 1977 report of the US Central Intelligence Agency which predicted that the Soviet Union would become a net importer of energy by the late 1980s, considerable effort has been put into official denials.

And yet in 1976 a major publicity campaign was launched to convince the population of the necessity to save energy in all its forms. According to official policy, this does not imply an energy crisis—it is simply intended to make people aware of the need to use the natural resources of the country "rationally". The policy-makers insist that sufficient energy resources exist, and any temporary set-backs are due to the geographical and logistical problems of exploiting them or, alternatively, slackness in some vital part of the energy industry or its auxiliaries.

Such slackness, even at the highest levels, is not to be tolerated. At the end of December, the Minister of the Coal Industry of the Ukrainian USSR was dismissed on the grounds that his ministry had been unable to rectify the production lag in the coal industry. For some years coal occupied a less elevated place in Soviet planning than other forms of energy, but it now appears to have been re-emphasised. Prospecting for new coal deposits has been going on, not only in the unexplored regions of Siberia, but also in the European parts of the USSR. During 1978, two major new coalfields were discovered at Lisichansk and Bogdanovskoe in Ukraine, conveniently close to traditional centres of industry. It is hoped both will be fully productive by 1985.

Unfortunately, most major energy sources in the Soviet Union are not so conveniently placed. The main centres of population lie west of the Urals; the new oil and gas fields lie far to the east. There are clear indications that the exploitation of these deposits is proving far more costly, both in money and in time, than was originally expected.

In January 1978, a group of foreign journalists on an official tour of the west Siberian oil fields, 'accidentally' met Sergei Velikopol'skii, First Secretary of the Communist Party branch at the administrative headquarters of the Samotlor field, the largest oil field in the Soviet Union. It is true, he admitted, that the output of the Samotlor field will level off over the next seven or eight years, and will then decline, but this will be more than offset by bringing the east Siberian fields on-stream. The fact that production from Samotlor will peak earlier than expected is merely due to the extreme climatic conditions encountered in the east Siberian fields. In order to meet production plans, more oil has had to be taken from Samotlor than originally projected for the current planning period.

In spite of the apparently optimistic tone of this interview, Velikopol'skii's remarks seem to suggest delays in the exploitation of the east Siberian fields. Permafrost or swampy terrain hardly provide optimum drilling conditions —although in the latter case, there has been encouraging progress in the use of slant drilling from artificial islands. Transporting the oil westwards is, however, an even more costly business. According to Academician Mikhail Styrikovich, it costs about 1 million roubles (a rouble is about $1) to lay 1 km of pipeline in this terrain, while the construction of workers' settlements costs 50—100% more than the construction of similar settlements in developed areas.

Sometimes, indeed, the logistics of oil extraction become ludicrous. At the Urengoi gas deposit, not only did the base camp have no proper maintenance facilities for equipment, all fuel for motor vehicles and tractors had to be hauled some 2000-3000 km, so that the transport costs exceeded those of the fuel itself. Only after some considerable time was it realised that motor fuel could be produced on site from the gas itself, and an experimental unit, capable of producing some 35 tonnes of fuel every 24 hours was installed on site.

Although unwilling to admit to an energy crisis, the Soviet authorities do admit, under pressure, to having underestimated their production costs This January Moscow radio, replying to an article in *Le Monde* which censured recent increases in the price of Soviet oil to the Comecon block, admitted an additional investment cost of 7,500 million roubles, simply to keep up the current level of supplies to Comecon. And this, it claimed, was in spite of there being no transport cost, since the outlay on the "Friendship" pipeline had already been recovered.

Furthermore, comparison of the official figure for pipeline built during the five-year-plan 1971-75 (12,000 km) and the amount of large-diameter pipe bought from abroad (1,000 million tons—sufficient to build some 13-15,000 km of pipeline, depending on wall-thickness), it would appear that the pipelines were at that time built largely from imported pipes. (The situation may have changed recently, judging from complaints last year that certain Soviet factories charged with producing the required pipes had failed to do so, thus delaying pipe-laying operations). Add to this auxiliary technology purchased abroad—high capacity compressor stations (Rolls-Royce), pumps for water-flooding techniques (US), desulphurisation equipment (France)—and the expenditure of precious foreign currency reserves must be considerable.

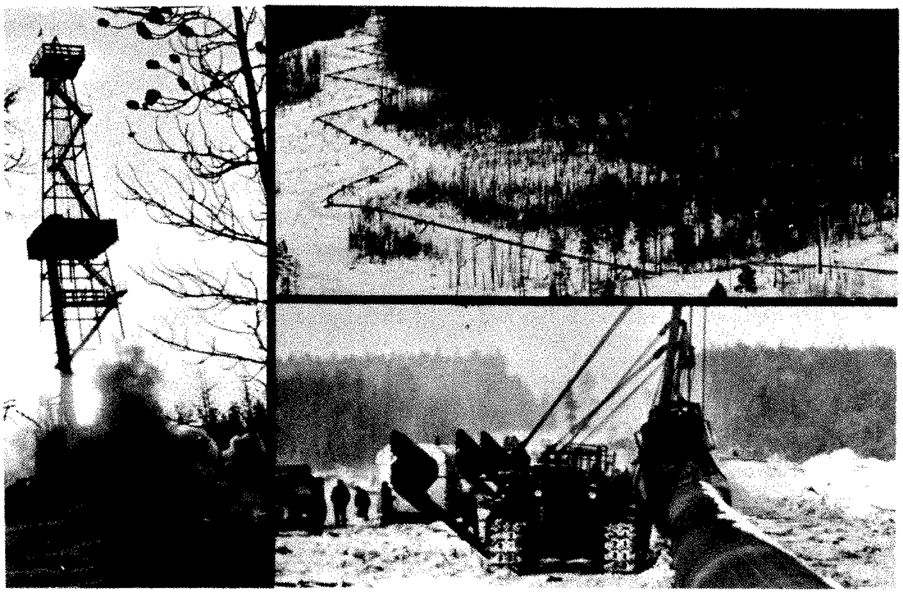
Even the Soviet Union's "prestige" position as major oil supplier to Comecon, has been falling since the sudden increase of oil prices to the bloc, in September 1976 (following pledges not to increase). While still paying lip-service to an integrated oil and gas policy for the Comecon bloc, a number of the individual countries are quietly pursuing their own alternative plans—East Germany the underground gasification of coal, Poland a country-wide survey for oil and gas resources, and Romania an off-shore drilling programme.

However, if the great pipelines, with their evocative names of "Friendship", "Brotherhood" and "Union" are more expensive as a means of integration than was first hoped, there still remains the new electricity link between Vinnitsya in Ukraine and the Comecon terminal at Albertirsa in Hungary. The Soviet Union has considerable plans for expanding generating capacity.

A unified power grid for the country is being completed, which would obviate any major differences in peak and non-peak hours. Since the Soviet Union is so wide east to west, there is virtually always a peak period going on somewhere in the country, to which electricity could be relayed from some less busy region. (The possibility of cryogenic superconductor transmission is seriously under consideration)

Speaking on "Power Workers' Day" last December, Petr S. Neporozhnii, the Minister of Power and Electrification, told *Pravda*, that in 1979, the generation of electric power is to be brought up to 1,265 GW, which would include an almost 50% increase in nuclear power generation.

The stress on the nuclear branch is not accidental In spite of the unified grid, it would clearly be more convenient to generate electricity close to where it is required. The major sources of fossil fuel for thermal power



Drilling in Siberia (left) is tough enough: then comes the problem of getting the gas and oil back to population centres.

stations, and the large rivers still not committed to their full hydroelectricity capacity lie far to the east—but a nuclear power station in the Soviet planners' opinion, can be built wherever required.

For the Soviet planners do not have to contend with an antinuclear lobby; even the dissidents seem to have accepted that nuclear power is an intrinsic good (unlike the Czech Chartists who recently demanded a referendum on the whole issue).

Repeatedly, official spokesmen stress that nuclear power stations are safe and do no damage to the environment. A book published in 1974 to celebrate 20 years of nuclear power generation did, indeed, contain a chapter on safety, but this only refers to radiation protection within the plant itself.

The Soviet planners seem convinced that no major accident can possibly occur. According to one US nuclear delegation, which visited the Soviet Union in 1970 "Reactor design is based on the assumption . . . that there is no credible accident corresponding to a severe accident excursus or total loss of coolant . . . The safety philosophy for light water reactors is similar to that for the LMFBR's in the USSR. For example, a double ended pipe break is considered incredible; therefore, no separate emergency core cooling systems, no containment buildings, no ice condensers, and no pressure suppresant chambers are provided".

With this somewhat casual attitude to safety, the Soviet Union is embarking on a major nuclear power programme. Last year new power sets were commissioned at the Leningrad, Novovoronezh, Chernobyl and Kursk power stations, and at present 13 nuclear power stations are under construction. Set capacity is to be increased from 440 MW to 1000 MW and there is even talk of sets of up to 2500 MW being feasible.

Most of the new stations are RBMK uranium-graphite boiling water reactors or water-cooled, water-moderated reactors. However, the present five-year plan commits the economy to the development and construction of fast-breeder reactors.

A pilot 12 MW fast breeder was constructed in Leningrad in 1968, and at Shevchenko, on the Caspian sea, a fast-breeder has been in operation since 1973, acting as the sole source of electricity and water desalination for the town. This was the reactor which in 1974 was observed by US surveillance satellites to have been damaged by an explosion although, according to official Soviet sources, their satellites failed to record anything amiss and the local population "did not even know that anything had happened". (Unofficial sources, however, reported considerable panic). Even when an off-the-record comment on the accident can be obtained, it is always presented as a small conventional explosion due to the contact of liquid sodium and steam in the heat exchanger—not properly speaking a nuclear event at all.

A second FBR being built at Beloyarsk was originally scheduled to be completed in 1973, but will probably be commissioned this year. Both these FBRs are uranium-based, but according to Mikhail Troyanov, Deputy Director of the Institute of Physics and Power Engineering "we see no difficulty in moving to plutonium. After 1990, breeders should be built in the USSR in large numbers".

Not only are the Soviet planners prepared to site power stations in centres of population; they are equally ready to use nuclear power to provide district heating, and as an industrial steam source. One such system is already operating at Bilibino on the Chukotka peninsular. Most commentators assume that such installations would be a combined source of electricity and heat, but mention has also been made of a special low-temperature, low-pressure water cooled reactor which could deliver 500 MW heat but no electricity, and which could possibly go into production at the beginning of the 1980s.

Against this background of expansion, there is a constant drive for more and more fuel economy. A number of less conventional energy sources are under investigation—windpowered generators are already being manufactured for use in the sheep-rearing areas of Moldavia and the far north, and the possibility of constructing solar power stations in the arid steppe is receiving serious attention. At the Institute of High-Temperature Physics, research is going forward (with US cooperation) on MHD generation as a means of utilising fossil fuels more efficiently.

The Far Eastern Science Centre is working on the possibility of using geothermal heat—in accordance with high level directives that they should devote their main attention to the problems and potentialities of their own area.

In spite of the expected advent of the supergrid, the possibility of pumped storage stations has not been overlooked, and the construction of such a station at Zagorsk was begun last September. And, since the fuel-saving campaign was inaugurated in 1976, (it was intensified in September 1978) there has been a constant discussion in the media of possible means of economising. These range from the domestic—one appeal on television to turn off unnecessary appliances is said to have saved 10 MW in a single hour—to new means of using fuel. The latter range from genuine savings—such as the saving of "more than 17%" of all thermal energy needs at the Kemerovo fertiliser works by using the heat from exothermic reactions, to advice about burning maizestalks or woodchippings, which seem more a symbolic gesture than a piece of practical economy.

Nor is the energy industry prepared to shoulder all the burden. One letter to *Pravda* from a manager in the Leningrad power industry suggested that it is not the power workers who should think of energy-saving, but the architects and designers. Their "window-mania" of the last few years, he claimed, has caused unnecessary increases of up to 60% in the cost of heating living and working space! □

correspondence

Short term contracts

Sir,—It is sad that three recent articles (23 November, page 310; 28 December, pages 743 and 745) on the difficulties facing research workers in universities have induced little dialogue in your correspondence columns. It has been our association's experience that there are at least two reasons for such a lack of response: (a) research scientists are often isolated in departments with a high percentage of tenured staff and think that protestation would have little or no effect; (b) many fear that if they do step out of line and "speak out" they will not only jeopardise their present job but will find it even harder to secure another. Presumably, it is because of this that the present appalling situation has been allowed to develop. We therefore would like to appeal to all researchers to start thinking positively, join a union and become active in it, join our association (if appropriate), or form an association and write to your MP, asking for an inquiry. We demand to have a career structure in research with some prospect of security so that a PhD will come to be regarded again as an attribute and not a liability!

Arleen Unger

ARMS, London, UK.

Sollas and the Sherborne bone

Sir,—I would like to correct the record of the Sherborne engraved bone controversy, unfortunately misrepresented in Dr L. B. Halstead's account of the late Professor Douglas's tape-recording linking Sollas with the Piltdown hoax (2 November, page 11). Douglas's story reveals nothing fresh except his own assumption that Sollas kept quiet about a 'hoax' at Sherborne School (Dorset) so that Smith Woodward might make a fool of himself; the rest is a tendentiously garbled summary of Bayzand's evidence against the bone in *Nature* 117, 233; 1926, confounded with facts stated by Smith Woodward himself (*Nature*, 117, 86; 1926).

Dr K. P. Oakley established in 1957 that the piece of bone was ancient and consistent with an Upper Pleistocene date. It is clear to the naked eye that it is semi-fossilised, as Smith Woodward claimed in his reply (*Nature* 117, 86) to Sollas's denunciation in *Ancient Hunters* (1924). Sollas (*Nature* 117, 233) was nonplussed by this claim and attempted to parry it with an ignorant remark betraying that he had never seen the object. Neither had Bayzand! Had he done so he could not have left Sollas in ignorance of a fact so vital to any assessment of a schoolboy hoax, or failed to investigate an ostensible fake of extraordinary ingenuity, as his wholly imprecise charge shows It is impossible to resist the conclusion that Bayzand heard a story, true or false, and simply did nothing at all—until 1914, as he himself tells us, when Smith Woodward's paper appeared (*Q. Jl. Geol. Soc.*, 70, 100–2).

It is generally supposed that Sollas and Bayzand were left with the last word, for Douglas evidently believed them, as did the late Joseph Fowler of Sherborne, whose exhaustive but uncompleted research led to my own interest in the affair. There was, however, a third letter in *Nature* (117, 341–2; 1926) only weeks later, from the supposed hoax victim, R. E. Steel, who began by apologising for Bayzand's having been misled by senior boys who had been unable to credit such a find by two 14-year-olds, Arnaldo Cortesi and Philip Grove, in their first weeks at the school. His account of the circumstances of discovery, corroborated by a former pupil who had recognised the character of the engraving and prevented Cortesi from throwing it into the day-room fire, and the aptness of the alleged site (thereupon efficiently investigated by Steel), are entitled to respect.

The question remains whether there was anything more than school rumour in the story Bayzand treated so casually but with such disastrous consequences for a potentially rare and interesting find. Was the engraving nevertheless faked, and if so, whence came the material and expertise? One can imagine Douglas's answer—one that would at least make sense of his otherwise forced analogy between Sherborne and Piltdown—but I hope shortly to deal more fully, in *Antiquity*, with this and other aspects of this curious tale.

R. A. H. Farrar

Royal Commission on Historical Monuments,
London, UK.

Seveso

Sir,—Professor Garattini and Dr Manara of the Istituto di Ricerche Farmacologiche Mario Negri, Milan, have accused me of underestimating the possible damage to human health caused by the Seveso accident (7 December, page 556).

I took on the assessment of the damage to health caused by the accident because I had been personally involved from the beginning in protection and prevention measures for the injured and for those still exposed.

I played an important role in the decision to evacuate the population of Seveso. This has been stated in several books on Seveso and in official documents in my possession. I never expected that readers of my papers would accept on sight my assessment of the consequences of the accident on the health of the population, and I have therefore always based my reports and conclusions on documents[1–10] which cannot be accused of prejudice in my favour. The great majority of these authors are either members of the Epidemiological Medical Commission of the Lombardy Region in Milan (of which Professor Garattini has been a member since its beginning) with responsibility for the health surveillance of the population, or of the Advisory Scientific Committee to the Italian Government in Rome for the Seveso accident (Commissione Cimino).

They have been (and still are) confronted with one of the most difficult and tricky problems in medicine. They have mastered the emergency with courage, skill and competence. The dermatological screenings carried out by them on 32,000 schoolchildren have no precedent in the history of clinical toxicology. I trust their reports to be accurate, meticulous and unbiased.

Nevertheless I may have overlooked or missed data available to Professor Garattini and Dr Manara which would prove me wrong. I therefore ask Professor Garattini and Dr Manara to make any such data known immediately, because only then (and not by saying that I am biased) will it be possible to evaluate the damage.

About 5.000 people are still exposed to levels of TCDD which, while admittedly lower than those of past cases of occupational exposure, could represent a potential risk. If my conclusions are wrong, we have a moral obligation to take protective measures immediately to prevent any further damage to this population.

G. Reggiani

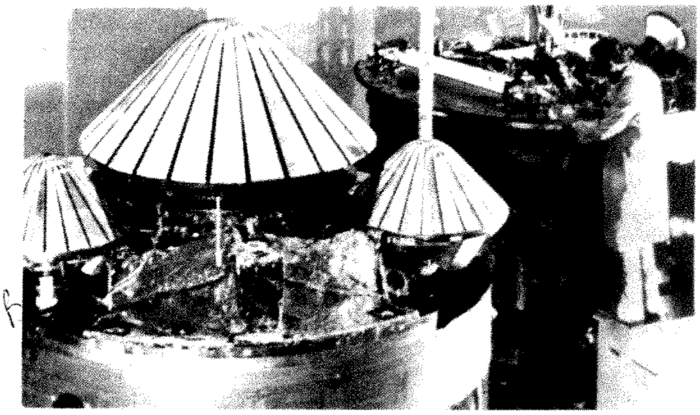
Epithelial cancer, differentiation, and vitamin A

from Brigid Hogan



MORE than 90% of people who die of cancer are killed by metastasising tumours of epithelial tissues. These malignancies do not develop rapidly, but evolve over one or two decades through stages in which there is increasing disorganisation of the epithelial layer and its association with the underlying stroma. Studying this latent period is like piecing together a complex and tantalising jigsaw puzzle; complex, because the pieces represent all the agents such as hormones, growth factors and tumour promoters which affect the proliferation, organisation and differentiation of epithelial cells; tantalising, because we obviously still lack many of the vital pieces needed to complete the picture and so perhaps learn how to intervene therapeutically between the initiating event and the final malignant state. One piece of the puzzle are the retinoids, a class of compounds based on vitamin A which for a long time has been known to have profound effects on many epithelial tissues.

Retinoids in organ cultures

The effect of retinoids on epithelial cells has been studied for many years. In young animals vitamin A deficiency results in the transformation of simple, ciliated, mucous-secreting epithelia (such as those found in the respiratory and genital tracts) into multilayered, non-secretory keratinised epithelia, a process known as squamous metaplasia. The change can be prevented (or reversed) by adding retinoids at concentrations down to about 10^{-10} M (see Clamon *et al.* *Nature* **250**, 64; 1974, for the standard assay using pieces of trachea from vitamin A-deficient hamsters). With higher concentrations of retinoids the tracheal cartilage starts to break down and proteases and hydrolases released from the chondrocytes begin to digest away the matrix. This response is usually considered to be simply the result of the detergent-like action of high concentrations of polar retinoids on the cell membrane, but others might argue that it reflects a physiological response of chondrocytes, important in tissue remodelling during early development. Of the natural retinoids, retinoic acid is the most effective in reversing squamous metaplasia and can be given in much higher doses as it is not stored in the liver.

Almost nothing is known about the way in which retinoids mediate their effect on epithelia. For example, they could act on the epithelial cells directly, or indirectly by provoking signals from the underlying stromal cells. It is possible that, like the steroids, the retinoids have to enter the cell to be effective; several cytoplasmic retinoid-binding proteins have been isolated from a variety of whole organs, and the affinity of one of these proteins for different analogues correlates with their effectiveness in preventing squamous metaplasia in organ cultures (Chytil & Ong *Nature* **260**, 49–51; 1976).

Retinoids and carcinogenesis *in vivo*

One of the most exciting new ideas in the study of retinoids is the possibility that they can intervene in the process of epithelial carcinogenesis *in vivo*. Several months after giving a dose of carcinogen to experimental animals, the target epithelium shows areas of disorganisation, ranging from hyperplasia (increased mitotic rate of the basal cells), squamous metaplasia and papillomas, to increasingly invasive carcinomas. A number of groups have reported that feeding the animals high doses of retinoids after the carcinogen treatment reduces the severity and often the incidence of the lesions in a variety of epithelial sites (for example, bladder, lung and trachea) (for reference, see Sporn *et al.* *Fed. Proc.* **35**, 1332; 1976). In these experimental systems, retinoic acid has proved to be more effective than other natural vitamin A derivatives. (Some workers have reported that retinoids have no effect on tumour incidence, but Sporn has argued that this is because retinol derivatives that can be removed from the circulation and stored in the liver were used). The action of retinoids therefore seems to be exactly opposite to the effect of tumour promoters—naturally occurring chemicals like the phorbol esters which do not themselves cause cancer but increase the rate at which tumours appear in response to carcinogen treatment (see *News and Views* **270**, 659; 1977). The retinoids, in other words, seem to be acting as 'anti-promotors'. But before readers run off to order mega-doses of retinoic acid, it must be stressed that the story is by no means simple, and there are reports that retinoids can enhance tumour growth, although in these cases the vitamin derivative was applied in high and possibly irritant doses to the skin rather than included in the diet (Polliack & Levij *Cancer Res.* **29**, 327; 1969; Polliack & Sasson *J. natn. Cancer Inst.* **48**, 407; 1972).

Retinoids and *in vitro* cell cultures

The problem with studying the action of retinoids *in vivo* or in organ culture is that there are too many pieces to the

---

Brigid Hogan is at the Imperial Cancer Research Fund Laboratories, Mill Hill, London.

0028–0836/79/0277—0261$01.00

puzzle. One way round this is to look at the effect of retinoids, either alone or in combination with purified growth factors and tumour promoters, on cell lines in culture, when there is only one target cell type. For example, retinoids can be shown to restore anchorage-dependent growth to some transformed cells (Dion *et al. Expl Cell Res.* **117,** 15; 1978) and inhibit the growth of melanoma cells (Lotan *et al. J. natn. Cancer Inst.* **60,** 1035; 1978).

In a recent paper, Todaro *et al.* (*Nature* **276,** 272; 1978) reported that retinoids inhibit the mitogenic effect of sarcoma growth factor (SGF) on a line of untransformed rat fibroblasts. Earlier studies had shown that SGF production is switched on when cells are transformed by murine sarcoma virus. The polypeptide seems to promote cell division (either in the same cells or in other, normal lines) by binding at the plasma membrane to the site normally awaiting the arrival of epidermal growth factor (in spite of its name, EGF promotes cell division in a variety of 'fibroblast' cell lines as well as in epithelial cells) It has been argued that tumour promoters mimic SGF and EGF by short circuiting the membrane–intracellular effector signal system (Lee & Weinstein *Science* **202,** 313; 1978), and the results of Todaro *et al.* suggest that the retinoids may block the circuit altogether. Although still very speculative this model accounts for the opposite effects of retinoids and tumour promoters *in vivo.*

As usual though, things are not as simple as they seem and far from antagonising the effect of various promoters, it seems that retinoids can act like promoters in certain systems. For example, Wilson and Reich have recently described a culture system in which retinoids act synergistically with phorbol ester and Rous sarcoma virus in stimulating plasminogen activator in chick embryo fibroblasts (*Cell* **15,** 385; 1978). Plasminogen activator is an extracellular protease which is assayed *in vitro* by its ability to digest a fibrin clot, but very little is known about its role in fibroblast behaviour in the whole animal. It seems very likely, for example, that the enzyme is important in tissue remodelling during growth and wound healing. Until more is known about the effect of retinoids on these processes *in vivo,* Wilson and Reich argue for caution in interpreting all results according to a simple model.

Indeed, the same issue of *Cell* adds another facet to the problem of retinoid action in the form of a paper by Strickland and Mahdavi on the effect of retinoids on the differentiation of murine teratocarcinoma cells *in vitro* (*Cell* **15,** 393; 1978). These authors claim that retinoic acid promotes the differentiation of F9 embryonal carcinoma cells into parietal endoderm cells, which normally synthesise plasminogen activator and large amounts of basement membrane material. Similar results have been observed in M. Sherman's laboratory using a variety of synthetic analogues of retinoic acid (Jetten & Jetten *Nature,* in the press). Although the results suggest that retinoids can increase the (normally low) probability with which F9 cells switch to endoderm, the possibility that they are increasing the survival of endoderm cells formed 'spontaneously' in the cultures has not yet been completely eliminated

Meanwhile, readers who find these multifarious results too indigestible might ponder on a paper by Graham *et al.* (*J. natn. Cancer Inst.* **61,** 709; 1978) who report a lower risk of cancer of the colon and rectum associated with high intake of green vegetables. □

Free-electron lasers

from J. D. Lawson

SOURCES of incoherent radiation have been familiar since scientific enquiry began; the generation of coherent radiation, on the other hand, is a relatively recent achievement. Fifty years ago, coherent radiation with frequency up to about 10^7 Hz was available, and in common use for radio transmissions. More recently, however, a series of inventions, culminating in the laser, have pushed the frequency up by many orders of magnitude to the ultraviolet region of the spectrum.

Devices invented during the past 40 years include the klystron, cavity magnetron, travelling wave tube, ubitron, ammonia maser and, at higher frequencies, the optical laser and free-electron laser. All depend on the stimulated emission of photons. If the photons interacting with the charges are real, they constitute a radiation field, and the device may be termed a 'laser'. In some systems the electrons are essentially free, or move in orbits determined by external magnetic fields; in others they are bound to atoms in gases or in solids. Some devices require a quantum mechanical description, whereas others do not. The first analysis of the free electron free-electron laser was in quantum mehcanical terms, but classical theory is sufficiently accurate and is now always used.

The operation of two systems described as free-electron lasers has been reported, one at Stanford University (Deacon *et al., Phys. Rev. Lett.* **38,** 892; 1977) and the other at the Naval Research Laboratory, Washington (McDermott *et al., Phys. Rev. Lett.* **41,** 1368; 1978) These devices operate in different regimes, and both form an interesting link between conventional lasers and microwave tubes.

In most microwave generators the beam interacts with single mode cavities, or with structures carrying a slow wave with longitudinal phase velocity close to that of the electrons. Such cavities and structures are limited to transverse dimensions of less than about a wavelength, and this imposes a lower wavelength limit of a few millimetres for reliable devices with useful power output. This limit may be avoided by making use of interaction with a 'fast' electromagnetic wave, which has phase velocity equal to or exceeding that of light. Such interaction necessarily implies a velocity difference between wave and particles; although not synchronous, coherent interaction can nevertheless be obtained by modulating the orbit of the electrons This principle (Gorn *U.S. Patent 2, 591,* 350, filed 1947) has been used in the 'ubitron' millimetre wave generator, (Phillips, *ITED,* ED-7, 231; 1960), and the free electron laser represents a special application for relativistic electrons when the fast wave is essentially a plane wave travelling along the axis. I shall now describe the Stanford scheme.

Suppose that a circularly polarised light wave of wavelength λ travels in the z-direction. A particle travelling along the z-axis experiences a transverse force which rotates with angular velocity proportional to the difference between the electron velocity and the light velocity. If now a twisted transverse magnetic field of periodicity D is introduced on the axis (with field vectors corresponding to the edge of the stairs in a spiral staircase) the

---

J. D. Lawson is with the Technology Division of the SRC Rutherford Laboratory.

particle is constrained to move in a spiral orbit If this spiralling is synchronous with that of the electric field vector as 'seen' by the particle, then coherent interaction and continuous energy transfer is possible. For highly relativistic particles moving in a helix of radius $r \ll D$, simple geometrical arguments show that

$$\frac{\lambda}{D} \approx \frac{1}{2\gamma^2}\left(1 + \frac{4\pi^2\gamma^2r^2}{D^2}\right)$$

where γm_0c^2 is the electron energy and $\gamma \gg 1$. Thus, for reasonable values of D, (a few centimetres), and γ of order 50–100, coherent interactions may be obtained in the infrared or optical region. Freedom from the limitations of slow-wave systems has, however, been bought at the expense of a relatively weak interaction. This is because the electric field is almost perpendicular to the particle orbit.

A beam of electrons moving at approximately the synchronous velocity exchanges energy with the wave; if the average particle velocity is slightly greater than the synchronous velocity, energy transfer from the particles to the wave is possible. Two regimes may be distinguished, the low current regime in which the wave interacts essentially with individual particles, (as in an accelerator) and a high-current high-gain regime where the plasma oscillation frequency in the beam is no longer negligible, and the interaction is with a space-charge wave travelling on the beam. The Stanford and Columbia-NRL lasers referred to earlier operate respectively in these two regimes, which can be described in quantum language in terms of Compton and Raman scattering.

The first demonstration of the interaction mechanism outlined above was by Madey and his team at Stanford in 1975 (*Phys. Rev. Lett.* **36**, 717; 1976). Making use of the superconducting linac there, which is able to provide a continuous succession of short high quality pulses of electrons, amplification of 10.6 μm radiation from a CO_2 laser was demonstrated. The twisted magnetic field of 0.24 Tesla was provided by a superconducting bi-filar helix, of 5 m total length. This experiment was followed in 1977 by a further demonstration, using the same magnet and accelerator, of a laser oscillator. Mirrors 12.7 m apart were placed symmetrically about the helix, and the electrons were steered by magnets to avoid them at either end. A mean power of 0.36 W was measured, corresponding to a peak power of 7 kW during the pulse. The wavelength was 3.14 μm, and the linewidth of 0.23% was determined essentially by the very short pulselength of 4 picoseconds.

Such a laser has the very attractive feature that it can be tuned by varying the electron energy. Unfortunately, however, the apparatus required is expensive, and the overall efficiency is low. Furthermore, the linewidth is rather broad for spectroscopic applications The use of a storage ring to recirculate the beam and thus raise the efficiency has been suggested. Unfortunately, passage through the laser induces energy spread in the beam and this greatly reduces the efficiency on subsequent transits. Whether, and if so how, this effect can be overcome is still a subject of active debate.

It is too early to forsee what the applications of this type of laser will ultimately be. More study, both experimental and theoretical, is required before realistic assessments of power and efficiency limitations can be made; the gain decreases rapidly as γ increases and it remains to be seen just how the various technical constraints conspire to produce a lower wavelength limit. Experiments are difficult, and progress may not be rapid.

The laser recently described by groups at Columbia University and the Naval Research Laboratory, operates in the collective regime. A rippled solenoidal magnetic field is used, and interaction is with the slow, negative energy space-charge wave on the electron beam. (The system may be viewed in a frame of reference moving with the electron as a parametric amplifier, in which the rippled field and space-charge waves play the part of pump and idler.) The current in this laser is 25 kA, (about 10^4 times that in the Stanford laser), but the energy is much lower, corresponding to $\gamma=3.2$. 1 MW pulses of radiation of length 20 ns and wavelength 400 μm were extracted through the hole in one of the mirrors. This is not the first observation of microwave power from intense relativistic beams in a rippled field; it is however the first time that a laser cavity has been used to provide feedback and enhance the output. The spectral bandwidth was 2%; this arises from the difficulty of maintaining constant beam conditions during the pulse.

Whatever the final applications of the radiation from these devices, (a topic not discussed in the papers quoted), they form a promising addition to the available range of submillimetre generators. The latest volume of 'Physics of Quantum Electronics' (**5**, Addison-Wesley, Reading, Massachusetts, 1978) devoted entirely to this field includes an interesting variety of points of view of the theory, and a historical summary. ☐

Contractility of the roots of flagella and cilia

from Michael Sleigh

A HIGH proportion of the basal bodies of cilia and flagella bear striated roots and/or bundles of microtubular fibrils. In the absence of clear evidence for any other function it has been assumed that the purpose of these attached fibrous structures is to provide a firm anchorage for the ciliary base, so that the propulsive activity of the ciliary shaft can be exploited to the full. However, large striated roots are present not only on mechanically active cilia and flagella, but also on such sensory cilia as those in the rod cells of the vertebrate retina, where anchorage of the ciliary base would not seem to require such a large root structure. The recent report by Salisbury and Floyd (*Science* **202**, 975; 1978) that the striated roots of flagella of the algal flagellate *Platymonas* undergo a calcium-induced contraction should provoke further investigation of these structures.

The variation in the spacing of the major bands of striated roots has puzzled some electron microscopists for about 20 years; not only is there a wide range of periodicities in different species, varying between about 12 nm and about 200 nm, but there are also variations within species of between 30 and 60 nm in *Trichonympha* (Pitelka & Schooley *J. Morph.* **102**, 199; 1958) and between 13 and 25 nm in *Naegleria* (Simpson & Dingle *J. Cell Biol.* **51**, 323; 1971) Many authors noted a superficial similarity to collagen in the periodicity and appearance of these fibres, since in many cases periodicities of between 60 and 70 nm with several intraperiod bands were found, but the detailed banding pattern is different and a biochemical analysis of roots from mollusc cilia by Stephens (*J. Cell Biol.* **64**, 408; 1975), revealed the presence of a novel type of protein (ankyrin) that could be separated as a doublet with molecular weights of 230,000 and 250,000. Each striated root is composed of a bundle of longitudinal filaments about 5 nm thick, sharing the common banding pattern.

The two striated roots of *Platymonas* pass from the basal body complex at the base of an anterior depression of

---

Michael Sleigh is Professor of Biology at the University of Southampton.

the cell across the centre of the cell close to the nucleus and terminate near the plasmalemma at the posterior end of the cell. The periodicity of these roots ranged from an extended spacing of 180 nm to a contracted spacing of about 60 nm. The longitudinal filaments were not visible in contracted roots, which were substantially (30%) fatter than extended roots. The extended pattern was seen in cells fixed after washing in artificial seawater lacking calcium or after washing in solutions containing EGTA, while the extreme contracted pattern was seen in cells treated with artificial seawater containing 2 mM $CaCl_2$; several other divalent cations were partially effective in causing contraction. Living cells observed in artificial seawater containing both 2 mM $CaCl_2$ and 5 mM ATP could be seen using the light microscope to undergo cyclic dimpling of the cell surface at sites of root attachment, and fixed cells from such experiments showed intermediate periodicities. This cyclical contractile activity of the striated roots is of particular interest, but the authors do not state its frequency, nor whether it coincides with any phase of the flagellar beat cycle. It is also of interest that the external application of ions and ATP is adequate to stimulate the contractile response in intact cells. The fully extended roots may be abnormal, since seawater contains calcium ions equivalent to about 10 mM $CaCl_2$.

Salisbury and Floyd suggest that the contraction of flagellar roots of *Platymonas* may have a function in the coordination or directional control of flagellar beating. This is interesting because in *Chlamydomonas* the two flagella are inserted at an angle, with the two basal bodies forming a V and a thick striated fibre (periodicity about 80 nm) connecting the upper parts of the two basal bodies (Ringo *J. Cell Biol* 33, 543; 1967). The response of *Chlamydomonas* to stimulation with calcium ions is a narrowing of the angle between the two basal bodies, perhaps by contraction of the thick striated fibre, and a transition from a 'breast-stroke' (cilium-like) beat that produces forward swimming to symmetrical undulations of the more parallel flagella that cause backward swimming (Hyams & Borisy *J. Cell Sci* 33, 235; 1978). It is also not impossible that the ciliary reorientation associated with the calcium-induced beat reversal of *Paramecium* could be associated with a contraction of the striated kinetodesmal rootlets (Naitoh *J. gen. Physiol.* **51**, 85; 1968).

Contractile activity of the striated roots of flagella and cilia of protists is in itself of interest, but if the striated roots of cilia in general are contractile, this finding could have wide implications, not least for sensory physiologists. For example, in the rod cells of the human eye a large striated root is attached to the basal body of the short cilium that connects the light-sensitive outer segment to the inner segment which leads to the sensory nerve; this root penetrates deep into the inner segment and ends in close contact with the plasmalemma of the inner segment. Some years ago Matsusaka (*J. Cell Biol.* 33, 203; 1967) showed histochemically that the ciliary roots in human rod cells possess ATPase activity. It may not therefore be too rash to speculate that the striated roots of the cilia in rod cells may be capable of contraction and that the cilium and its contractile root may be concerned in the transmission of information from the photoreceptive membranes of the outer segment to an electrically excitable membrane of the inner segment. ☐

Mediaeval meteors

from David W. Hughes

ASTRONOMICAL historians have been doing well during the past year, one of the high spots being the solution of a famous longstanding problem. No report had come to light in Europe and the Near East of any observations of the Crab supernova explosion which the Chinese apparently saw with great ease; it was first recorded on 4 July, 1054 and was so bright that it could be seen during the day-time for 23 days. K Brecher, E. Lieber and A. E. Lieber solved this puzzle (*Nature* **273**, 728; 1978) by finding a reference to the supernova in a biographical encyclopaedia of physicians written in about 1242 by Ibn Abi Usaybia. The compiler told how Ibn Butlan, a Christian physician, had seen the supernova when he was staying in Constantinople and had regarded it as being the cause of an epidemic which lead to the death of many thousands of people at that time.

A less newsworthy but more typical example of the work of the astronomical historian has been published recently in the *Journal for the History of Astronomy* (**9**, 123; 1979). Umberto Dall'Olmo has scoured the European annals and chronicles that have been collected in the *Monumenta Germaniae historica* and the *Rerum Italicarum scriptores* and has compiled a list of all the meteorites, meteors and meteor showers that occurred before 1500 AD and were regarded as being of sufficient importance to be recorded for posterity.

Dall'Olmo emphasises that his list is by no means complete. First it is obvious that many events went unrecorded. Second it is a hopeless task to examine all the historical and literary texts which mention astronomical events. The discovery of the Arabic record of the Crab supernova nearly a millenium after its occurrence is ample evidence of that.

Considering these facts it is fair to ask if lists of ancient astronomical events are of any use to the present astronomical community. The answer is an unequivocal yes. The period of accurate photographic and telescopic observations is so short in comparison with the age of civilisation, never mind the age of the Earth, that anything that extends this period is worthwhile. For this reason alone people have been searching for records of solar and lunar eclipses, comets, aurora, sunspots and meteoric phenomena. In the specific field covered by Dall'Olmo the occurrence, strength and date of meteor showers are vital parameters in a study of the perturbations that the causative meteor streams suffer during their lifetime in the Solar System. Meteor streams are moved by the gravitational attractions of the major planets and obviously can be detected from Earth only when the stream crosses the Earth's orbit.

These ancient records also provide a fascinating insight into the interests and priorities of the astronomers of the time. Meteors were regarded as ominous omens, but due to their brief duration they were only minor omens in comparison with solar eclipses and comets. A great shower in March 763 was interpreted as 'a forecast of the end of the world'. On 17 October, 855 meteors shot westward across the sky all night and 'for this reason Emperor Hlotarius prayed, neglecting all his affairs'. Man's great desire to link cause and effect is illustrated by the account of the fireball seen on 11 August, 1353 which left behind an ash-coloured vapour, twisted like a snake. The chronicler stresses that 'after its appearance it did not rain for three months' On 14 December, 1482, a very bright meteor was seen again in Parma, 'flying in a clear sky, and without noise —but there was an earthquake'...

It is also heartening to realise that meteorites were treasured in those days, just as they are now One that fell in Catalogne during 1348 was sent to the King on the back of a mule. A meteorite as large as the head of a man fell near Altesleibon in Germany in 1136, and 'the brothers of the abbey kept it carefully'. We read of a

---

David W Hughes is a lecturer in the Department of Physics at the University of Sheffield.

0028-0836/79/0277—0264$01.00

meteorite which fell in 586 'roaring with sparkles'. But my favourite account is of a rather unusual 'lapis mirae magnitudinis'. 'A stone as large as a house fell near Duringia, Germany in 1135, with a terrible noise that lasted for three days. The lower part of it, about half, sank into the ground, burning for three days like steel from the fire'. Also on July 26, 1243 'so many stars fell that if they had been true stars none would have remained in the sky'.

It is apparent that, in addition to their scientific worth, these historical papers are a source of some marvellous quotations. □

Man and desert

from Peter D. Moore

THE problems associated with the spread of deserts are both social and ecological. The involvement and interest of man in the process of desertification made it an appropriate subject for consideration at the Tenth International Congress of Anthropological and Ethnological Sciences*. It is also appropriate that it should have formed the theme of a post-plenary session entitled, 'Anthropology and Desertification' and have been held at the Central Arid Zone Research Institute (CAZRI), Jodhpur, for this institution has contributed much to the understanding of, and attack upon, desertification in the Rajasthan Desert of north-west India.

Complex historical and economic factors have contributed to human mismanagement of marginal arid lands. The indigenous peoples of the Rajasthan Desert, according to H. S. Mann and S. P. Malhotra (CAZRI), have many traditional techniques for coping with semi-arid conditions, including mixed farming, fragmented land holdings (of advantage in scattered rainfall areas), fallow and rotational farming systems, migration in famine, as well as socioreligious customs and taboos, particularly in relation to the care of trees. Modern desertification problems in the area may well be due to the imposition of new pressures rather than the long-term persistence of old ones.

A similar note, although with an economic overtone, was struck by B. Spooner (University of Pennsylvania). The modern economic system operates at a level greater than that of the ecosystem. Market forces are now the chief determinants in societies where once kinship and local organisation were most influential. Such a situation will encourage short-term exploitation of the local resources. Equally, the operation of rational, political processes at the new level may appear quite irrational at the ecosystem level. For this reason, even when ecological solutions to desertification problems can be envisaged, they may be difficult to implement locally. Historically, arid lands have often been politically independent and socially there may be resistance to innovative ideas from outside. It is vital, therefore, that the formulation of environmental policy should receive contributions from the indigenous society.

A novel and valuable feature of this conference was the involvement of anthropologists, environmental scientists and pastoral economists. The result was an unusual, yet productive, juxtapositon of disciplines and ideas. Among the pastoral economists, the contribution of S. Sandford (Overseas Development Institute, UK) is worth particular mention. He described pastoral systems as being either conservative or opportunistic. In the former, the number of grazing animals is kept at a constant, fairly low level. Since in most semi-arid areas there is considerable fluctuation in rainfall (and, therefore, in forage production) from year to year, the conservative system of pastoralism will keep overgrazing to a minimum, but will fail to exploit all of the available forage in a good year. An opportunistic system, on the other hand, varies the number of animals maintained according to the conditions prevailing. This should provide greater production efficiency, but in practice the number of stock is often reduced too little and too late, with consequent overgrazing and starvation. Environmentalists therefore tend to favour conservative strategies, but one is faced with the question of just how high the stock density should be set. In other words, how frequently can one tolerate the temporary over-exploitation of resources? If the answer is very infrequently, then stock density must be kept low, much of the resource is under-exploited and the entire system becomes far less attractive to the pastoralist than an efficiently managed, opportunistic system.

Specialised field studies and case histories in semi-arid areas are contributing much to understanding local problems. Several papers derived from a multi-disciplinary study of the Turan Biosphere Reserve of north-eastern Iran, a project directed by Spooner. C. Hamlin (University of Pennsylvania) described the use of satellite remote sensing for the detection of changes in vegetation and sand distribution. A. E. Nyerges has examined the feeding behaviour of sheep and goats, which are herded in mixed flocks in the Turan. Adult goats proceeded at a rate of 25 m min^{-1} whilst feeding and this allowed them to range further from villages when foraging than sheep, which proceeded at 17 m min^{-1}. Kids achieved only 14 m min^{-1}. The result of these different speeds is that a zonation of grazing pressures exists around villages and pens, in which distant areas are predominantly grazed by goats. The selectivity of the two animals also varies, for example, *Artemisia* comprises 23% of the sheep's diet, but only 15% of the goat's intake. Thus, both qualitative and quantitative variations in vegetation predation exist at different distances from a village.

A further pressure on vegetation associated with human settlement is the demand for fuel wood. M. Martin has estimated that a family requires 150 kg wood each month. The processing of milk products from a flock of goats

Peter D. Moore is a Senior Lecturer in the Department of Plant Sciences, King's College, London.

---

*Held in Delhi on 12–18 December, 1978. It was convened by B. Spooner (University of Pennsylvania) and H. S. Mann (Director of CAZRI).

A hundred years ago

IN connection with our article last week on a proposed Scottish observatory, it may be interesting to state that one day last August Mr. Milne Home, chairman of the Meteorological Society for Scotland, accompanied by Mr. Colin Livingston, headmaster, Public School, Fort William; Mr. Thompson, student; and Mr. David Doig, contractor, ascended Ben Nevis and made several observations with the view of erecting a station on the summit. They found the top enveloped in a mantle of snow—a circumstance which rendered it an extremely difficult task to select suitable spots for the erection of a dwelling-house and observatory. After a careful survey Mr. Home came to the conclusion that the plateau immediately beyond the spring affords the best site. The recommendation this spot has is its contiguity to the water-supply. It is proposed to construct the buildings after the following plan: first, a wall of stone with an inside lining of wood and an inner coating of felting, and the outside of the wall to be covered with corrugated iron. An external wall of stone would also be erected to serve as a protection from the blast. The estimated cost of the structure is 500*l*.

and sheep may require as much as 100–150 kg each day. Thus the total pressure is considerable in a habitat where, according to R. Bhadresa (King's College, London) the woody biomass above ground is only about 2,600 kg ha^{-1}.

One conclusion which emerges from an interdisciplinary study of this sort is that the ecological questions, such as those concerning the extent of human impact, are relatively easy to answer compared with the social problems which are likely to arise if attempts are made to reduce this impact. ☐

Galaxy clustering and anti-clustering

from William C. Saslaw

THE positions of galaxies on the sky contain much important astrophysical information. First, their spatial distribution provides a link with the conditions of their formation and the large scale expansion of the Universe. Second, their distribution may show evidence for haloes of absorbing gas or dust around galaxies Interesting developments are occurring in both these areas.

In the standard view of our expanding Universe, galaxies formed at a redshift $Z \lesssim 10^3$, after matter and radiation decoupled. We do not understand the detailed manner of their formation, nor do we know their initial distribution in space. Having formed, however, galaxies interact gravitationally as massive point particles and we can follow their changing distribution from some assumed initial state. The encouraging result is that the simplest initial state—a uniform random distribution—can lead to the main properties of the non-uniform clustering we now see.

This clustering of galaxies was first observed by Herschel and analysed by von Humboldt (*Cosmos*, 1866) even before they knew the nature of the nebulae. More recently, one of the most useful measures of clustering has turned out to be the two-point galaxy correlation function, $\xi (r)$, discovered by Totsuji and Kihara (*Pub. Ast. Soc. Japan* **21**, 221; 1969) who analysed the Lick survey of galaxies brighter than 19th magnitude. They found that the difference between the observed probability of finding a galaxy at distance r from any arbitrary galaxy and this probability in a uniform random distribution, varies approximately as $r^{-1.8}$ over distances between about 0.5 and 10 megaparsecs. Their results have since been confirmed and extended by many astronomers, especially Peebles and his collaborators at Princeton.

To help understand these observations, several theoreticians working mainly with N-body computer codes developed by Aarseth at Cambridge have simulated the clustering of point masses in expanding universes. One of the major questions is to discover what ranges of initial clustering spectra and expansion rates are compatible with the observed two-point and higher order correlations. A forthcoming paper by Efstathiou (*Mon. Not. R. Astr. Soc.* **186**, 133; 1979) helps to clarify this question. He computed two 1,000-body clustering problems. Both started from exactly the same Poisson initial distribution. One evolved in a closed Einstein–de Sitter universe (which has density parameter $\Omega = 1$). The other evolved in a more rapidly expanding open universe which started with $\Omega = 0.775$ and ended with $\Omega = 0.1$ after the expansion radius had increased by a factor of 31. The galaxies in the closed universe evolved into a distribution $\xi (r) \sim {}^{-1.8}$ after the universe expanded to several times its original radius. This agrees with several previous simulations by others. The galaxies in the open universe, however, had a somewhat steeper correlation function at each stage of its expansion. Thus at any given chronological time, the expansion rate seems to be mirrored in the galaxy correlations.

Taken at face value, this would support the view that we live in a closed universe. However, as Efstathiou recognises, this would be a premature conclusion. One reason is that fluctuations of ~ 0.2 in the exponent of $\xi (r)$ are found among different 1,000-body simulations using the same initial statistical (but not identical) distribution To reduce these 'ensemble fluctuations' one needs to use more particles. At present it is possible to compute $\sim 4{,}000$-body problems in reasonable time using direct integration methods There are plans to evolve about 20,000 bodies using Fourier techniques under conditions suitable for finding two-particle correlation functions, and these should produce results soon. Another difficulty is to sort out the results of different initial distributions of galaxies. Here one especially wants to learn whether the initial distributions which would evolve into the observed distribution using a rapidly expanding open universe need to be very *ad hoc*. In the more distant future, enough galaxy redshifts could be measured to make use of constraints from velocity correlations as well as spatial correlations.

We turn now to a second aspect of the galaxy distribution: anti-clustering. Unlike the positive correlations just discussed which are found using a huge sample of galaxies, anti-clustering may be found among small subsets. These subsets make a negligible contribution to the overall correlation function, but are of special interest on their own. In particular, if there is a relative deficit of distant galaxies around nearby ones, the most plausible explanation would be an obscuring halo of gas or dust around each of the nearby galaxies. Such haloes, with a mass at least several times the mass in the easily visible body of the galaxy, have become fashionable in recent years as a means of stabilising spiral galaxies against the formation of a bar in their centre. It is now doubtful whether such a massive halo is really necessary for stability. This stability can also be provided by counterstreaming stars (Kalnajs, *Astrophys. J.* **212**, 637; 1977; Zang & Hohl *Astrophys. J.* **226**, 521; 1978) which remain from mergers which formed the galaxy, or by a concentration of mass in the nucleus of a galaxy. Moreover, it is not clear that the nonlinear results of instability to bar formation, possibly followed by a transition to spiral or elliptical structure in an explosion or gravitational encounter, are inconsistent with observations Nevertheless, the existence of galactic haloes remains an important question. For example, if most galaxies have haloes of about 10 times their presently observed mass, it would strengthen the evidence that we live in a closed universe.

Direct evidence for haloes could come from faint optical or X-ray emission around galaxies, from the rotational velocity of neutral hydrogen clouds around galaxies, and from gas or dust around nearby galaxies which absorbs the light of more distant galaxies. Observations with the first two techniques suggest that haloes do exist around some galaxies, but their masses are very uncertain. In the case of optical or X-ray emission we do not know the mass/luminosity ratio. This ratio depends on both the composition and geometric distribution of material in the halo. With neutral hydrogen clouds, the masses can be determined more accurately but the observations are not easy to make. They suggest haloes of moderate mass.

The third technique, galaxy anticlustering, has not been pursued vigorously This is because, until very recently, there was not a large enough

complete sample of galaxies with known distances in which to look for statistical anti-clustering between near and distant galaxies. The relative distances had to be estimated from rather fickle secondary indicators such as apparent magnitude or size. Using these secondary indicators, Bogart and Wagoner (*Astrophys. J.* **181,** 609; 1973) found weak evidence for anti-clustering between near and distant rich clusters of galaxies, and Wesson (*Astrophys. Lett.* **19,** 127; 1978) has claimed to find this effect among 274 bright galaxies in the local supercluster. Now, however, many more galaxy redshifts are becoming available and they will enable much better analyses of anti-clustering based on distance to be made. Sandage (*Astrophys J.* **83,** 904; 1978) has published 719 redshifts for galaxies in the local supercluster, and more are to come. Recently Vera Rubin of the Carnegie Institute in Washington DC has compiled a list of lists of redshifts published in 1976–1978 and of measurements in progress. More than 5,500 redshifts were published in this period and a roughly equal number should be measured in the next year or two. This will be a sample to conjure with. In addition, powerful new machines, such as the one which Kibblewhite and his associates are completing in Cambridge, will determine the positions and characteristics of galaxies on photographic plates rapidly and automatically. Thus in the years just ahead we can expect to understand much more about the distribution of matter over the largest scales of the Universe.

Gravitational waves confirmed at Texas Symposium

from M. C. Begelman, A. C. Fabian, N. A. Sharp and A. Wakelin

THE peripatetic Texas Symposium on Relativistic Astrophysics went to Munich in 1978* with, for the first time, participants from the People's Republic of China. Traditionally, the symposium is not regarded primarily as a forum for announcing the latest results, but more as a chance to review the progress of the past 2 years. With several exceptions—notably the new findings on the binary pulsar and the discovery of a new type of emission-line object—this meeting largely followed suit.

The first day was devoted to extragalactic sources, which, to the relativistic astrophysicists, meant quasars, BL Lacertae objects, and Seyferts. There was little theoretical debate, black holes and beams are seemingly well entrenched as the current fashion, and most of the reported progress was observational. It seems that the defining characteristics of the various types of object are still controversial. Several speakers (and recent observations) suggested that common classification schemes, based on spectral signature, may be misleading. For instance, it seems that all Seyferts may radiate the bulk of their energy in X rays, and, so far, there are three known X-ray quasars. Infrared also figured strongly, but sadly there was no discussion of the wealth of ultraviolet data now available from the IUE satellite.

Of particular cosmological interest was the report on the microwave background, devoted mainly to the very careful work of D. P. Woody and P. L. Richards of the University of California Lawrence Berkeley Laboratory. The spectrum now appears to be only approximately black body with a temperature of ~3K, being instead too peaked and too narrow. This deviation cannot be explained by any of the processes currently expected to produce deviations. Further theoretical work and further observations will doubtless be available by the next Texas meeting.

There was also a very lucid review by G. F. R. Ellis (University of Capetown) of the many assumptions and corrections which are made by cosmologists when considering the available data. Although much of this is known to the expert practitioner it deserves a wider audience amongst all people collecting and interpreting data of cosmological interest.

It was not until halfway through the conference that classical relativity theory made its appearance, with a clear discussion by J. Ehlers (Munich) of the difficulties of treating isolated systems. This is of great importance in the interpretation of the binary pulsar.

The common meeting ground for relativists and astronomers is this binary pulsar. Discovered in 1974 by Hulse and Taylor, the pulsar swoops around its companion in a highly elliptical orbit at velocities ~0.1% of the velocity of light. J. Taylor (University of Massachusetts at Amherst) reported the detection of four more relativistic effects, the most exciting of which is the confirmation of the existence of gravitational waves. He announced the measurement of the advance of periastron (similar to the excess advance of the perihelion of Mercury attributed to relativistic effects) at an earlier Texas conference. Refinements in the measuring equipment and techniques have allowed Taylor, and his colleagues L. Fowler and P. McCulloch, to improve the timing accuracy of the pulse arrivals by a factor of 20. An iterative method has then been used to obtain corrections up to the third order in (v/c).

In particular, the rate of decrease of the orbital period is observed to be $\sim -3.2\times10^{-12}$ s s^{-1}, and is of the correct sense and magnitude to agree with the general relativity prediction of energy and angular momentum loss by way of gravitational radiation. The importance of gravitational radiation in causing the spiralling together of binary companions has long been realised in the evolution of close non-pulsar binary system. This is the first time that a quantitative measurement has been made. The binary pulsar is apparently turning out to be a remarkably clean laboratory for relativistic astrophysics. Further work, especially theoretical, will, it is hoped, check all other possible causes of the observed effects and refine the measurements already made. The current data restrict the masses of the pulsar and its companion to around 1.4 $M_\odot$ each, consistent with a pair of neutron stars, or a neutron star (the pulsar) and a white dwarf. Changes in the observed pulse shape hint at spin-orbit coupling causing the pulsar spin axis to process.

J. Nelson (Lawrence Berkeley Laboratory) reported on an optical object found by Crane within 0.3 arcsecs of the position of the binary pulsar. If it is the pulsar, then the pulsed fraction is less than 1%, and if it is the companion then it must be hotter than ~18,000 K in order to be able to radiate the observed flux without causing an excessive periastron advance.

The discovery of the most unusual stellar spectrum of 1978 was undoubtedly reported by B. Margon (University of California, Los Angeles). The 14th magnitude emission line object numbered 433 in the catalogue of Stephenson and Sanduleak shows emission lines that move across the spectrum! These strong features have been seen to shift by up to 600 Å (an equivalent velocity shift of ~0.1 c) in 30 days. SS433 has been the subject of intense study recently since it was

realised that it was associated with a variable radio source (see for example Clark & Murdin, *Nature* **276**, 44; 1978; Ryle *et al. Nature* **276**, 571; 1978). An X-ray source A1909+04 is also in the right position and it is located in line with the supernova remnant W50. Margon and his colleagues are the first to observe the unusual optical emission features. Two in particular lie either side of Hα, the infrared one of which moved to longer wavelengths by 150 Å, the red feature moving in the opposite sense by 70 Å, in just four nights observing. SS433 presents a challenge; perhaps it too will become a regular at the Texas conferences. □

Pathogenic mechanisms of mycoplasmas

from D. B. Archer

MYCOPLASMAS are a diverse group of wall-less prokaryotes. They have been implicated as possible causal agents in a multitude of diseases in animals, plants and insects, but have been demonstrated to be causative in relatively few instances and in only a handful of cases is there any information which bears directly on the pathogenic mechanisms involved. However, from the Proceedings of the 2nd Conference of the International Organisation for Mycoplasmology (IOM) (*Zentralbl. Bakt. Parasitnek. Infekt. Hyg.* **241**; 1978) it is clear that an understanding of the pathogenic mechanisms is now being worked towards.

The diversity in form of mycoplasmas reflects the range of diseases and mechanisms involved. Some mycoplasmas are motile and motility may be necessary for these organisms to reach their target site, although a non-motile variant of *Spiroplasma citri* is known to be pathogenic when injected into host phloem cells by an insect vector (Townsend *et al. J. gen. Microbiol.* **100**, 15; 1977). Mycoplasmas lack flagella and their mechanisms of motility are poorly understood although an actin-like protein has been reported in *Mycoplasma pneumoniae* (Neimark *Proc. natn. Acad. Sci. U.S.A.* **74**, 4041; 1977). However, Rodwell *et al.* (*IOM Proceedings*) showed that no mycoplasma protein co-electrophoresed with rabbit muscle actin by two-dimensional gel electrophoresis. Although Rodwell *et al.* could not detect a mycoplasma protein having a high affinity for deoxyribonuclease 1, a characteristic of eukaryotic actin, Kahane *et al.* (*IOM Proceedings*) were able to isolate a multiprotein complex having a high affinity for muscle myosin.

Attachment to host cells is of primary importance in the pathogenicity of *Mycoplasma gallisepticum* and *M.pneumoniae*, among others. A *M.pneumoniae* membrane protein (P1) is required for the attachment to host tracheal cells (Hu *et al. J. exp. Med.* **145**, 1328; 1977) and although these workers could not detect any staining of *M.pneumoniae* proteins with PAS, a carbohydrate stain, it is of interest to know whether P1 is identical to the recently isolated glycoprotein from *M.pneumoniae* (Kahane & Brunner *Infect. Immun.* **18**, 273; 1977) because carbohydrate has been implicated in the attachment of this organism to host epithelium (Powell *et al. Infect. Immun.* **13**, 959; 1976). Apart from the presence of a glycoprotein in *M.pneumoniae*, and possibly *M.gallisepticum* (Goel & Lemcke *Ann. Microbiol.* **126**, 299; 1975) there are no confirmed reports of glycoproteins in any other mycoplasmas. If carbohydrate is important in the host cell attachment of other mycoplasmas it need not be through a glycoprotein and Huang (*Nature* **276**, 624; 1978) has recently pointed out that glycolipids can be involved in cell adhesion, although glycolipids do not seem to be involved in the host cell adhesion of *M. pneumoniae* (Hu *et al. op. cit*). Both *M. pneumoniae* and *M. gallisepticum* adhere to erythrocytes and this attachment has been used as a convenient model for natural host cell attachment. It seems that glycophorin is the major erythrocyte receptor for *M. gallisepticum* (Banai *et al. IOM Proceedings; Infect. Immun.* **21**, 365; 1978) whereas this is not the case with *M. pneumoniae* (Feldner *et al. IOM Proceedings*), although bindings of *M. pneumoniae* to host epithelial cells is reduced by pretreating host cells with neuraminidase (Powell *et al. Infect. Immun.* **13**, 959; 1976; Gabridge, *IOM Proceedings*). These mycoplasmas also bind to glass and plastic so it is of interest to know what determines specificity of binding *in vivo*. Sialic acid is of importance in the binding of *M.gallisepticum* to erythrocytes but this residue alone probably could not provide specificity of host. Isolation of the presumed binding proteins of mycoplasmas and determination of their affinities for target sites would enable some judgements to be made on the specificity of mycoplasma–host cell interactions.

Host cell attachment may not be as important in determining specificity as the production of a mycoplasma toxic substance or susceptibility of the host to it. Indeed, there is no evidence for high affinity host cell attachment by most mycoplasmas. Unfortunately, information on toxic products of mycoplasmas is meagre. Hydrogen peroxide and ammonia are produced by some mycoplasmas and may be toxic factors, particularly if the association of the mycoplasma with the host is intimate (for example *M. pneumoniae*) or if the amount of hydrogen peroxide is large (*Mycoplasma mycoides* subsp. *capri*). Specificity may more easily be explained by the production of a toxic compound which has selectivity of action, but little information on such substances is available. Characterised toxic cell products are the galactan of *M.mycoides* subsp. *mycoides* (Lloyd *et al. J. med. Microbiol.* **4**, 425; 1971: Buttery *et al. J. med. Microbiol.* **9**, 379; 1976) and the exotoxin of *Mycoplasma neurolyticum* (Tully, *INSERM* **33**, 317; 1974). Also, low molecular weight toxins have been isolated from *S.citri* (Daniels & Meddins *INSERM* **33**, 195; 1974: Daniels *IOM Proceedings*). One hopes that purification and characterisation of such toxic products will lead to experiments designed to determine their modes of action. Exotoxins were not detected, however, in culture filtrates of *M. gallisepticum*, an organism known to be neurotoxic (Thomas *Ann. N.Y. Acad Sci.* **143**, 218; 1967). Some mycoplasmas bind to and transform lymphocytes (Ginsburg & Nicolet *Nature new Biol.* **246**, 143; 1973; Cole *et al. IOM Proceedings*; Wise *et al. IOM Proceedings*) and form caps (Stanbridge *IOM Proceedings*; Stanbridge & Weiss *Nature* **276**, 583; 1978) demonstrating mitogenic activity *in vitro*. Also, Cole *et al.* (*IOM Proceedings*) reported that mycoplasmas induce the release of cytotoxic factors from lymphocytes. The *in vivo* importance of mycoplasma interactions with lymphocytes is unknown but provides a plausible explanation for many of the effects of mycoplasma infection.

In conclusion, although information on the pathogenic mechanisms of mycoplasmas is still limited the situation is improving. Specificity remains a major problem which can only be overcome by characterisation of the cell residues involved in host cell attachment of those mycoplasmas which do attach, and by isolation and characterisation of toxic factors. Demonstration of *in vivo* mitogenicity would clearly be a major advance in our understanding of the pathogenic mechanisms of mycoplasmas. □

Lowland Maya radiocarbon dates and the classic Maya collapse

Raymond Sidrys & Rainer Berger

Departments of Anthropology, Geography and Institute of Geophysics, University of California, Los Angeles, California 90024

Three processes of the Late Classic Maya collapse, the demise of the stela cult, the breakdown of elite culture, and the reduction of the commoner population, are compared by frequency-distribution bar-graphs of dated monuments in the Southern Lowlands and radiocarbon dates from elite and commoner contexts. The demise of the stela cult and the breakdown of elite culture seem to have coincided. The commoner radiocarbon bar-graph does not necessarily indicate the occurrence of a major demographic catastrophe.

THE Late Classic Maya collapse poses one of the most challenging problems in world archaeology. Briefly, it represents an abrupt cessation of Lowland Maya elite class culture—particularly such activities as the use and production of carved and dated monuments, platform-temples, elaborate residential structures, fine polychrome pottery, and carved jade—during the ninth and early tenth centuries AD. The demise of the elite class was apparently accompanied by a rapid and large-scale depopulation of the commoner class, particularly in the Southern Lowlands (eastern Chiapas, the Peten and western Belize).

Our study is intended not to explain the events of the collapse, but to empirically measure the rate of decline in several cultural processes integral to the collapse. Three phenomena of particular interest are the cessation of the 'stela cult'; the decline in the general activities of the elite class; and the apparent population reduction of the commoner or peasant farmer class. For each of these cases we have produced a 'decline curve' that is based on a frequency-distribution bar-graph of relevant chronometric data, namely the dedicatory Long Count dates inscribed on monuments, and radiocarbon dates from elite or commoner contexts.

Traditional theories have tried to explain the collapse from either an internal or external orientation[1,2]. The internal theories emphasise either natural catastrophes such as overpopulation, soil exhaustion, disease, earthquakes, hurricanes, climatic change, and insect pests; or socio-political crises such as peasant revolts and intersite warfare. The external theories view the collapse in terms of cultural developments, such as military or economic events, throughout the whole of Mesoamerica. Unfortunately, the majority of these hypotheses are speculative single-cause theories which are not supported by statistically valid empirical data.

A new research phase on the Maya collapse was initiated in 1970 at a seminar by the School of American Research, Santa Fe, New Mexico[3]. The theoretical model, summarised by Willey and Shimkin[4], is tailored to future hypothesis-testing. This model states that certain activities of the elite class which had successfully stimulated the growth of Early Classic Maya civilisation became inappropriate for a new Late Classic society faced with a burgeoning population, precarious agricultural production, and military harassment by central Mexican groups. The cumulative effect of these disrupting factors was to administer a fatal shock to the Maya political system. The demise of the elite class is thought to have been marked by the erection of the last calendrically dated stelae at Seibal and Uaxactun in AD 889 or in Tonina in AD 909; the termination of monumental architecture at Tikal in AD 830, Altar in AD 909 and Seibal in AD 928; and the appearance of the Tepeu 3 ceramic horizon in the ninth century AD that signalled the end of the Peten polychrome tradition and the appearance of foreign fine paste wares. Following the tenth century no general recovery of Classic Maya civilisation took place in the Southern Lowlands. Some pockets of elite tradition continued to exist, however, along with reduced commoner populations, at such sites as Tikal, Altar and Seibal[4].

Analysis of stelae dates

The Sante Fe model relies heavily on stelae dates to construct a chronology for the collapse of the Maya elite. Yet it fails to provide a comprehensive frequency-distribution of Lowland stelae erection. This is done in the following section, as a test of the Santa Fe model.

The erection of stelae and altars was an important activity for the Classic Maya. The labour necessary for the erection of these multi-ton limestone monuments ensured that the stela cult crosscut Maya religion, politics and economics. The quarrying and sculpting, for example, was probably done by professional masons and artisans. Many dozens, and sometimes several hundreds, of labourers had to drag the megalith to the site. The average Peten stela had a mass of about 5 metric tonnes, while the largest in the Lowlands (stela E at Quirigua) had a mass close to 50 tonnes[5]. The elite no doubt maintained a high visibility as the organisers of this impressive operation—because precisely such displays of power helped to maintain their authority. The upright rectangular stela, featuring a life-size low-relief portrait of the ruler, often colourfully painted, had a hieroglyphic text with such information as the ruler's genealogy and the dates of his accession to the throne, marriages, battles, and so on. Smaller cylindrical altars, usually with a shorter text and less sculptural ornamentation, were placed in front of the stela. In addition to their role as a power displays for the elite, the stelae and altars also had important religious functions. They were usually erected on 'period-endings' that commemorated important calendric periods such as Katuns and Hotuns (9.9 yr). Their hieroglyphic texts contain substantial technical information on calendars and other ritualistic activities. Finally, ceremonial caches were frequently buried underneath or alongside the stela. These monuments clearly served as foci for both political and religious activities.

0028-0836/79/0277—0269$01 00

The number of dated Maya monuments, both stelae and altars, erected in the Southern Lowlands per Katun cycle (19.8 yr) during the period AD 292–909 is shown in Fig. 2. The span of time ranges from the erection of the earliest long count-dated stela yet found in the Lowlands (Tikal St 29) at AD 292, up to the last securely-dated Lowland stela at Tonina. Graphs similar to Fig. 2 have been previously published[6–8] but to our knowledge Fig. 2 is the most comprehensive for the Southern Lowlands. It includes 415 Long Count dates, most of them period-endings, marked on 359 stelae and 56 altars from 62 sites. The boundary for the Southern Lowlands is marked in Fig. 1. Southern Lowland sites from which we obtained either stelae or altar dates for our study are marked in Fig. 1 by a triangle, while sites that furnished radiocarbon dates are marked by a star. The area that we have marked as the Southern Lowlands is almost identical to that used by the Sante Fe Seminar[3]. (The stelae data[5] were obtained from the literature and also from personal communication with J. Graham and I. Graham.)

Recent evidence suggests the possibility that Protoclassic rulers (AD 100–250) of Highland Guatemalan centres, such as Kaminaljuyu, exported the stela cult to the Lowlands by military conquest or marriage alliance[9]. Figure 2 shows that few dated monuments were erected in the Lowlands before AD 475 (9.2.0.0.0.). Sites with these early monuments are clustered within a 30 km radius in the north-east Peten. Following the major waterways, however, the stela cult moved rapidly into neighbouring regions and by AD 534 (9.5.0.0.0.) the maximum geographical spread for Classic Maya stelae had been reached[10]. Shortly afterwards the growth of the cult was slowed by a brief and enigmatic hiatus that lasted from AD 534–613 (9.5.0.0.0.–9.9.0.0.0.) which apparently was caused by the withdrawal of Central Mexican political influence in the Peten[11].

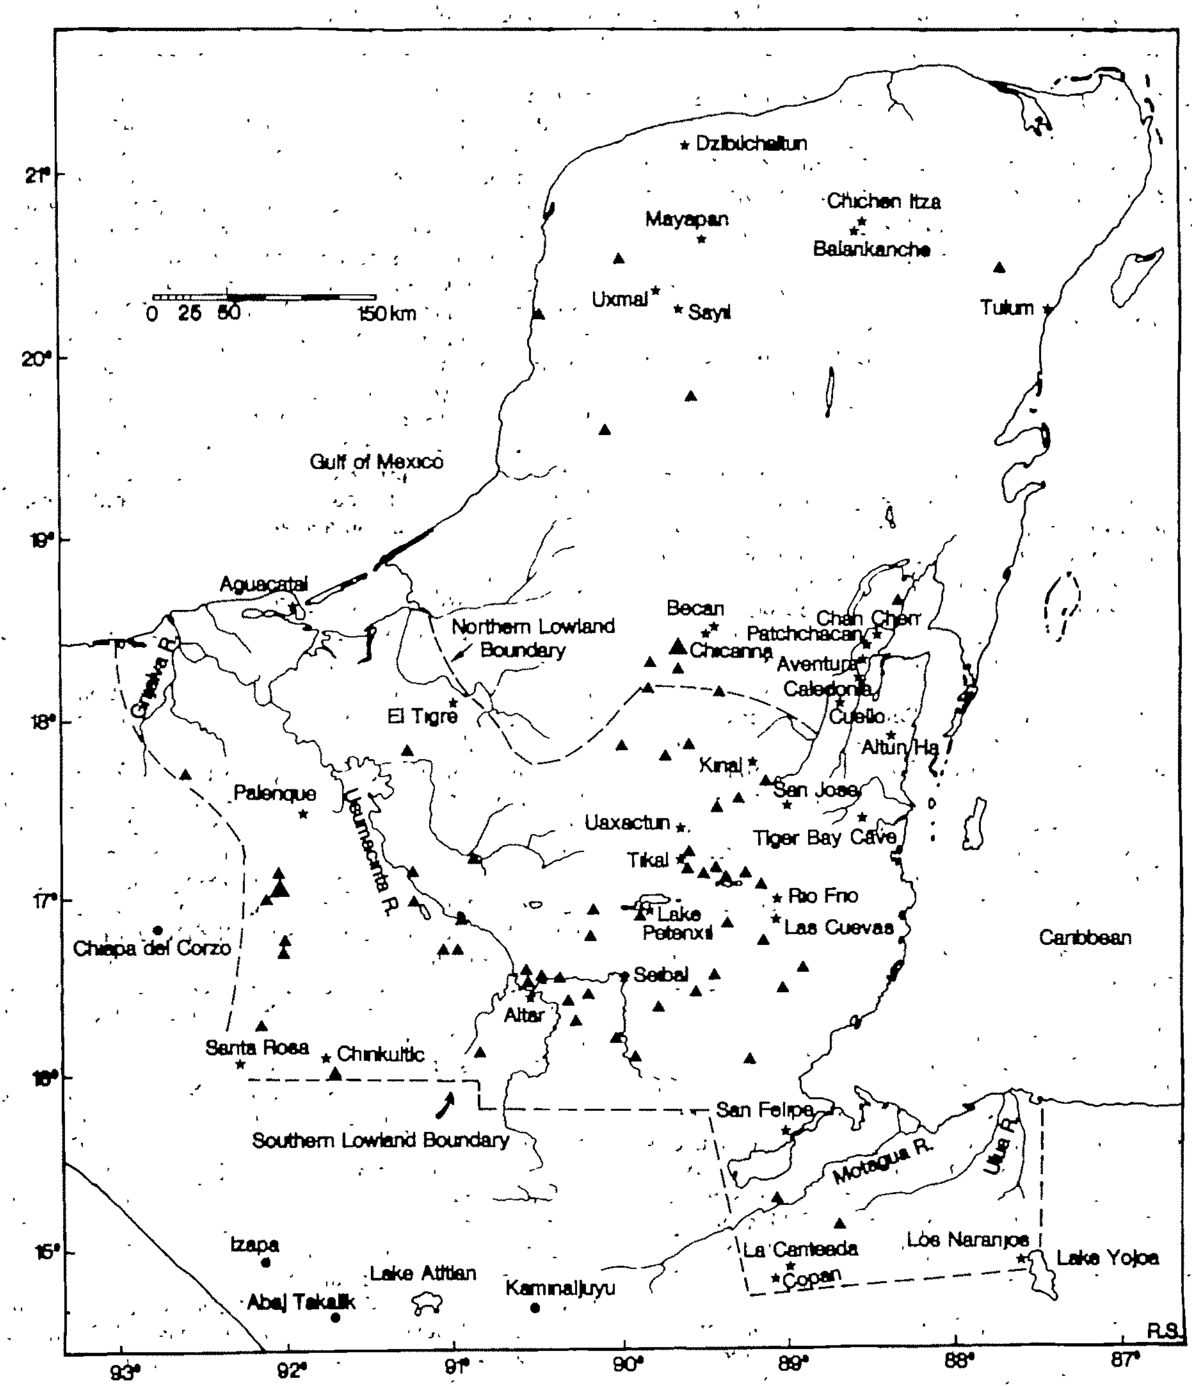

Fig. 1 Map of Maya Lowlands showing sites with dated monuments and radiocarbon dates. Only Southern Lowland sites were used in study. Note both long count dates and radiocarbon dates were used from Tikal, Uaxactun, Palenque, Seibal, Altar and Copan. The last Terminal Classic stelae were erected at Tonina, Chiapas and San Lorenzo, Campeche (sites marked by large triangles).

The explosive growth of the cult during the period AD 613–790 (9.9.0.0.0.–9.18.0.0.0.) is clear in Fig. 2. During this period at least 324 stelae and altars were dedicated in both the Southern and Northern Lowlands. The climax of the stela cult was reached in the eighth century. This zenith can be measured by several statistical conventions. The mean stela date, calculated from a sample of 300 stelae, is AD 705 (ref. 5). The date AD 731 (9.15.0.0.0.) is the statistical mode, as it occurs on more monuments than any other period-ending[12], while the date AD 790 was commemorated by at least 19 ceremonial centres, more so than any other period-ending[6,7].

The popularity of the cult took a sudden downwards plunge at AD 810 (9.19.0.0.0.). Its rapid decline culminated with the erection of the last securely-dated stela at Tonina, Chiapas in AD 909 (10.4.0.0.0.) (I. Graham, personal communication). We include in Fig. 2 an even later stela at San Lorenzo, Campeche which has been dated by J. E. S. Thompson to AD 928 (10.5.0.0.0.)[13]. Its absolute date cannot be established conclusively, however, as it bears only a floating Calendar Round date.

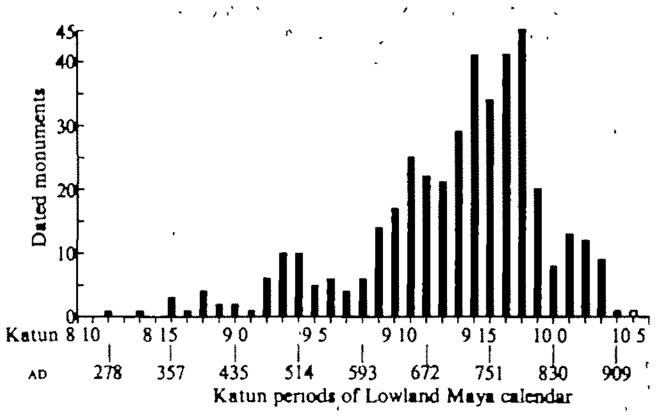

Fig. 2 The number of dated monuments erected per Katun period in the Southern Maya Lowlands. All monuments that were erected during a given Katun period are indicated in the position directly above the start of the Katun. Included are: 415 LC dates carved on 359 stelae and 56 altars from 62 Southern Lowland sites.

Figure 2 shows that a genuine collapse or abrupt breakdown of the stela cult occurred, rather than a gradual or normal decline in popularity, by both the asymmetry of the distribution and the steep downslope. The growth and maturity of the cult lasted some 500 yr, whereas its decline took place in about a century. This sudden loss of an established tradition of ruler glorification does favour the demise of the rulers themselves and their entourage.

Bar-graphs of radiocarbon dates

In their model Willey and Shimkin[4] found that the degree of commoner population decline following the loss of the elite was the most formidable research problem of the Maya collapse. They did not specify the exact degree to which populations of the Southern Maya Lowlands either died out or migrated. Adams, on the other hand, apparently relying on ceramic evidence, has estimated that an unusually rapid depopulation from 3,000,000 to 450,000 took place in the countryside and at ceremonial centres in a period from 75 to 100 yr (ref. 14). Similarly, Culbert offers a population loss for the Lowlands in excess of a million people within a century and describes it as one of the world's greatest demographic disasters.

In his synthesis of ceramic chronologies for the Santa Fe Seminar, Rands demonstrated that in general the average Maya ceramic period lasted 75 yr, with an uncertainty of ±30 yr for either the beginning or ending date[8]. Thus ceramically-based population studies at any given Maya site can only suggest that a house mound had been occupied during part or all of a 75 yr period. A further complication is the problem of the terminal stratigraphic layer, which in many cases represents the transitional Late Classic–early Postclassic occupation of the site. This stratum is particularly troublesome because it lacks a bordering stratum that can fix an incontrovertible upper temporal limit[3].

Frequency-distribution bar-graphs of Lowland Maya radiocarbon dates offer an alternate or supplementary dating method necessary in establishing rates of decline for non-stelae dated Late Classic elite activities and the relative population size of the commoner class. A large number of Maya radiocarbon dates already exist, and many others could be readily obtained from the hundreds of skeletons and charcoal samples that have been collected and stored during major Maya field projects by Canadian, American, Mexican and Guatemalan academic institutions. The average range of uncertainty associated with Maya radiocarbon dates so far collected is of the order of ±80 yr, which is similar to the time span of the average Maya ceramic phase.

To determine whether elite activities in general did undergo a radical decline at the same time as the collapse of the stela cult, we have produced a frequency-distribution bar-graph of 96 radiocarbon dates whose archaeological context represents various Southern Lowland Maya elite activities. Figure 3*a* shows the frequency of these activities through the period 51 BC to AD 1389. These activities, as dated by the ^{14}C method, include the inhabitation of palaces, the building of platform-temples and palaces; the production of sophisticated carved wooden lintels for palaces and temples; the production of elegant wooden figurines and bark-paper codices; and the administration of cave ceremonies and elaborate burials.

Most of the 153 radiocarbon dates in Table 1 have already been published and were compiled through an intensive search of the literature. Table 1 also includes 22 previously unpublished ^{14}C dates from Tikal, Guatemala, that were measured by the University of Pennsylvania Radiocarbon Laboratory (W. Coe and E. Ralph, personal communication). Table 1 is intended to be a comprehensive list of most of the ^{14}C dates presently available from the Maya Lowlands during the period 51 BC to AD 1389. Accordingly, it contains an additional 27 dates from the Maya Northern Lowlands that are not plotted in Fig. 3*a*, which are marked by an asterisk. Table 1 gives the archaeological provenience of the ^{14}C sample and classifies this provenience into an elite or commoner context. The classification was made by us on the basis of the excavator's description of the excavation context. All radiocarbon dates, whether previously published or not, were converted to tree-ring calibrated dates using the chart of Suess[16,17]. For purposes of standardisation the calibrated date was rounded to the nearest interval of 50. Accordingly our calibrated date may differ slightly from previously published versions. Any other

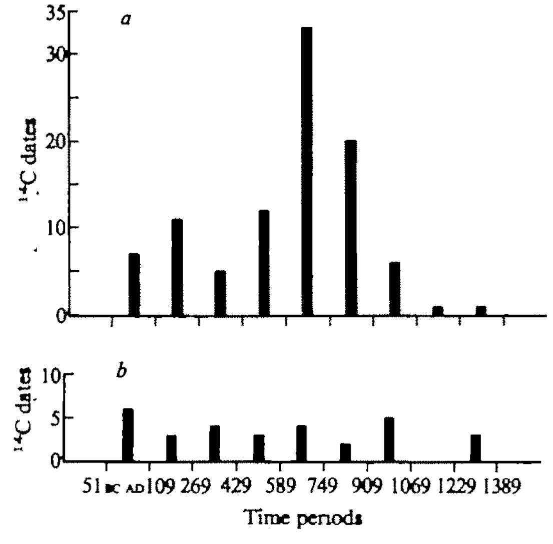

Fig. 3 *a*, Radiocarbon dates from elite contexts in the Southern Lowlands per time period; *b*, Radiocarbon dates from commoner contexts in the Southern Lowlands per time period.

calibration can be based on the BP radiocarbon date in Table 1. For some samples we have assigned a time range or several date possibilities instead of a single date. This situation exists because the calibration curve is not always singularly definitive. In plotting these cases on Fig. 3*a* we used either the midpoint of the range or the average of alternate dates. Table 1 also specifies the material composition of the radiocarbon sample, the laboratory number of the processed sample and the published reference.

Figure 3*a* indicates that Maya elite activities are present throughout the time span 51 BC to AD 589 (the Protoclassic and Early Classic periods) and their relative frequency shows only minor fluctuations. Elite activities dramatically increase during the period AD 589–749, and attain their zenith during this point. A significant decrease of these activities is observed during the period AD 749–909, followed by a drastic decline that takes place from AD 909–1069. Maya elite culture in the Lowlands during the period AD 1069–1389 is almost negligible.

The asymmetry and steep downslope in Fig. 3*a* clearly demonstrate a breakdown of elite class culture during the tenth century in the Lowlands, and its cessation, for all practical purposes, by AD 1069. The decline curves presented in Figs 2 and 3*a* are remarkably similar. A minor difference is that elite culture declines somewhat later than does the stela cult, a lag of the order of about one century. This was also noted by Hammond at Pusilha, Belize[18]. However, as Fig. 3*a* involves a broader spectrum of individuals and activities than Fig. 2, this time lag is expected. It is reasonable to conclude that the graphs in Figs 2 and 3*a* are measuring somewhat different aspects of the same phenomena—the rise and fall of the Classic Lowland Maya elite class. The similarity of the two graphs helps to establish the reliability of the ^{14}C frequency-distribution bar-graph method.

As previously discussed the depopulation rate of the Lowland centres, following the collapse of elite culture, is the most difficult problem of the Maya collapse. Figure 3*b* shows the distribution frequency of 30 ^{14}C dates, within the span 51 BC to AD 1389, that are from what may be called Southern Lowland Maya commoner contexts. In other words they are not inherently associated with elite manifestations. The ^{14}C samples come from commoner contexts that include house mounds, burials, middens, ridged fields, and lake sediment deposits which contain maize pollen as evidence of nearby agriculture.

It is immediately apparent that Fig. 3*b* indicates mildly fluctuating population cycles in the Lowlands, but no radical growth spurts or drastic declines. A slight population decline

* The radiocarbon date is not plotted in Fig. 3*a*, *b*, either because it is in the Northern Lowlands or it falls outside the range 51 BC to AD 1389.

† Date is rounded off to nearest 50

‡ Half life 5,568±30 yr.

might be indicated for the period AD 1069–1389, as only three ^{14}C dates are present, but given the overall small sample size this is hardly evidence of a major demographic catastrophe for this period. Figure 3*b* does not establish, then, a depopulation curve similar to those previously demonstrated for the cessation of the stela cult and general elite activities during the Late Classic–Terminal Classic periods.

The lack of a collapse curve in Fig. 3*b* may be due to the relatively small sample size or perhaps indicate a historical fact. In particular, the sample used is three times smaller than that in Fig. 3*a* and about 12 times as small as that in Fig. 2. A further complication is the geographical context of the ^{14}C samples. Only 35% of the dates come from the Peten, while the rest are from adjacent areas such as Belize, Chiapas, and Honduras, areas that may have been the scene of a delayed collapse[4]. Unfortunately the 30 dates represent most, if not all, of the ^{14}C dates presently available from Lowland commoner contexts. We therefore urge Maya archaeologists to obtain more commoner-associated ^{14}C dates, as these dates should eventually be of great value in resolving the depopulation issue and be more representative of the cultural situation as it actually was. Yet we also wonder if any major depopulation would not have been apparent in the 30 dates obtained so far.

A critical reexamination of the depopulation problem has in fact been offered by J. E. S. Thompson[19] who concluded that wholesale desertion of the Central area at the close of the Classic period can be ruled out. He proposed that a Postclassic population, probably reduced in size, had continued to exist in the Central Lowlands in isolated villages. This population was depopulated, in turn, during the first 50 yr of contact by Europeans, due largely to newly-introduced diseases such as dysentery, hookworm, and malaria. Additional support for a rethinking of the depopulation issue is found in Hellmuth's bibliography of the post-Conquest Lowland Maya[2] and in a recent article by Adams and Smith that compares the extensive population decline in mediaeval Europe to that of the Late Classic Maya[21].

The decline curves for the cessation of the stela cult and the breakdown of general Late Classic elite activities seem to be very similar, although the latter process continued for another century following the demise of the stela cult. The ^{14}C bar-graph that simulates the population level of the commoner class during this period does not, however, indicate the occurrence of a major demographic catastrophe.

We thank Drs N. Hammond, H. B. Nicholson and G. Willey for helpful comments, Dr John L. Sorenson for Mesoamerican ^{14}C dates, Dr Thomas A. Lee Jr, for dates obtained by NWAF, Drs William Coe and Elizabeth Ralph for 22 unpublished radiocarbon dates from Tikal. Parts of this study were supported by the NSF.

Normal human tissues contain RNA and antigens related to infectious adenovirus type 2

Normal human tissues have been found to contain RNA which hybridises with four regions of the adenovirus type 2 genome, including one which contains the transforming gene(s) of this virus. The RNAs have also been extracted from gorilla organs, but not from those of chickens, suggesting that they are a feature of all normal higher primate tissues. Serological tests suggest that these homologous RNAs are translated into proteins connected with essentially normal and virus-infected cell functions.

THE adenoviruses[1,2] are associated with respiratory infections in humans. Many serotypes of these viruses can induce tumours in rodents[3–6], and adenovirus type 5 transforms human cells in culture[7]. During studies on human cancer, we have investigated the possibility that human tissues might contain RNA sequences related to human DNA viruses, using the technique of *in situ* hybridisation[8–10]. We have found that normal human tissues contain RNA that hybridises with four regions of the genome of adenovirus type 2 (Ad-2). One of these regions includes the transforming gene(s) of this virus[7,11,12]. This suggests either that genes similar to viral transformation genes are present in man in

0028–0836/79/0277—0274$01 00

much the same way that the avian *sarc* genes are homologous in base sequence to the *src* (transforming) gene of the Rous sarcoma virus[13,14], or that infectiously acquired Ad-2 DNA can persist under host control. The human cells expressing the RNAs in greatest abundance seem to be solitary, possibly circulating cells. Human tissue cultured cells apparently do not contain an abundance of these RNAs, which may account for the fact that they have not been described previously.

Hybridisation studies

In looking for possible RNA sequences related to Ad-2 viral DNA in uninfected human organs, we initially used placenta as the RNA source because it is available in quantity. Moreover, fetal tissues are often associated with endogenous viral sequence expression[15–17]. Total RNA was extracted by standard procedures[18] and iodinated[19] with ^{125}I for use in hybridisation. Equal amounts of Ad-2, human DNA and λ phage DNA or Ad-12 DNA were denatured and spotted on nitrocellulose strips and hybridised by the usual procedure[20] (for details see legend to Fig. 1). *Escherichia coli* total ^{125}I-labelled RNA served as an RNA control, hybridised to a parallel series of spots but substituting *E. coli* DNA for phage DNA. The hybridised strips were then treated with RNase and, after suitable washing, were dried and autoradiographed on presensitised X-ray film (Royal X-omat XHI Kodak) at −70 °C in cassettes fitted with intensifying screens. Such spot tests are extremely sensitive and the amount of signal due to hybridisation or to background is immediately visually apparent. Hybridisation can be quantitated if necessary by cutting out the spots and scintillation counting. This procedure was followed as described later to construct melting-temperature curves of the hybrids.

After autoradiographic exposure, there was no trace of hybridisation to phage DNA. In fact, the spots containing this DNA were, if anything, below background radioactivity levels in some cases, suggesting that the bound DNA may have preempted potential binding sites for molecules that contribute background. There was, as expected, very strong hybridisation to human DNA. Ad-2 DNA showed moderate hybridisation (Fig. 1*a*), which easily reached autoradiographic saturation on prolonged exposure (Fig. 1*b*). Ad-12 DNA showed a barely detectable autoradiograph (not shown). *E. coli* ^{125}I-labelled RNA did not hybridise with any of these DNAs, but did so with *E. coli* DNA.

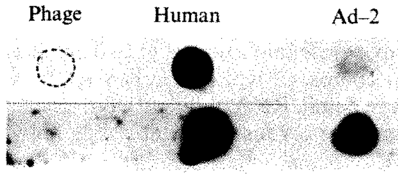

Fig. 1 Spot tests of hybridisation of ^{125}I-labelled human placental RNA to DNA of λ phage, human and adenovirus type 2 (Ad-2). The location of the negative hybridisation is shown by a dotted circle. Hybridisation has occurred to human DNA and to a lesser, but definite, extent to Ad-2 DNA. The conditions for hybridisation were as follows. The DNA samples were brought to the same concentrations, and 1-μg aliquots bound in spots to a strip of nitrocellulose filter by the method of Gillespie and Spiegelman[20]. The filter strip was then incubated for 6 h at 68 °C in 6 × SSC containing 0.02% each of Ficoll, bovine serum albumin (BSA) and polyvinyl pyrollidone (PVP). It was then transferred to 3.6 ml of this same solution containing 2 mM, EDTA, 0.5% SDS and ~7×10^7 c.p.m. of placental total RNA previously prepared[18] and radiolabelled[19] with ^{125}I. The mixture was annealed at 68 °C for 15–16 h, cooled rapidly and the filter strip washed in 2 × SSC, treated with RNase (40 μg ml^{-1}, 1 h, 37 °C in 2 × SSC), washed in 2 × SSC, treated with pronase (400 μg ml^{-1} in 2 × SSC, 1 h), incubated in 2 × SSC, 0.5% SDS for 6 h at 68 °C, washed exhaustively in a large volume of 2 × SSC, dried in a vacuum oven and autoradiographed for (*a*) 10 d, (*b*) 3 weeks at −70 °C using Kodak Royal X-omat XHI X-ray film presensitised by brief exposure to light from a calibrated masked flash gun.

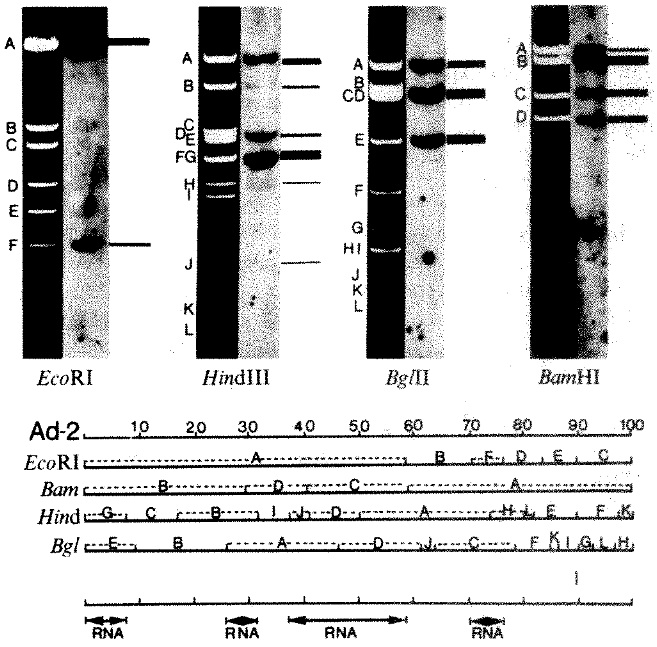

Fig. 2 Restriction digests of Ad-2 separated into fragment classes by electrophoresis on agarose gels stained with ethidium bromide and photographed in ultraviolet light, are shown paired with autoradiographs of ^{125}I-labelled placental RNA hybridised to the same fragments after transfer to nitrocellulose filter membrane and hybridisation as detailed in the legend to Fig. 1, and in the text. The bands in the digests are identified by letters to the left of each gel track. For technical reasons, the smallest restriction fragments do not photograph satisfactorily, and some of the minor autoradiographic bands are difficult to detect consistently together in the same autoradiograph. Because of this we have included a third track which indicates, diagrammatically, for each enzyme digest, all the bands to which we have obtained hybridisation in replicate experiments. These data are also shown below the photographs in the form of maps of the positions of the restriction fragments obtained with each enzyme in relation to the Ad-2 DNA map, which is divided into 100 fractions, according to the usual convention. The restriction fragments which hybridise with placental RNA are indicated for each digest by dotted lines over the fragment concerned. From these data, the provisional assignments have been made for the maximum limits to the Ad-2 genome sequences which hybridise with human total RNA; these are represented as double-ended arrows below the relevant locations. The conditions for electrophoresis were 1% agarose gels run at 40 V for 10 h, or 80 V for 4 h, in a buffer containing 15 mM Tris, 18 mM NaH_2PO_4, 0.5 mM EDTA, *p*H 7.8.

These results indicated that Ad-2 DNA contained some sequences homologous with human RNA, although they did not show whether these might have arisen from possible contaminating host cell sequences. Nevertheless, the fact that Ad-2 and Ad-12 were grown in similar human cells but behaved differently on hybridisation with human RNA suggested that contamination was unlikely. To investigate this point, we hybridised the same DNAs after digestion with the restriction endonuclease *Eco*RI, which cuts λ and adenovirus DNAs into small numbers of fragments; these can then be separated on agarose gels and transferred to nitrocellulose strips by the Southern procedure[21] for subsequent hybridisation with the same ^{125}I-labelled human RNA probe. After autoradiographic exposure there was hybridisation only to Ad-2 DNA and this was limited to the *Eco*RI A and F fragments (Fig. 2). Separate lots of Ad-2 DNA were then cut with three further restriction endonucleases, *Bam*HI, *Bgl*II and *Hin*dIII, which are known to produce genomal fragments overlapping and different from those produced by *Eco*RI. Hybridisation of human placental ^{125}I-RNA to these sets of fragments, as before, yielded the following hybridisation data (Fig. 2).

The fragments that hybridised were *Eco*RI A and F; *Hin*dIII A, B, D, FG, J and H (the latter two very faintly); *Bgl*II A, CD and E; and *Bam*HI A, B, C and D. These data define the following provisional maximum limits for the hybridising regions. As only the A and F fragments of *Eco*RI hybridised, all the observed hybridisation must lie within these limits. As *Eco*RI A, *Bam*HI B, *Hin*dIII G and *Bgl*II E fragments hybridised, but *Hin*dIII C or *Bgl*II B did not, the left end of *Hin*dIII C defines the most rightward limit of the first region of hybridisation at 7.5 units on the Ad-2 map[22]. This region, from 0 to 7.5, is known to contain the transforming gene(s)[23]. Because the *Bgl*II B fragment did not hybridise, but the *Bgl*II A fragment did, the latter, with the other restriction enzyme fragments that overlap it, defines the beginning (left end) of the next region of hybridisation at approximately 26 units. *Hin*dIII I did not hybridise but *Hin*dIII J did, so the I fragment defines a non-hybridising gap, and the left end of J defines the beginning of the next region of hybridisation at approximately 37 map units, extending to approximately 58.5 units, which is defined by the left end of *Eco*RI B, which did not hybridise. By the same reasoning the *Eco*RI F fragment must define the limits of the fourth region of homology as between approximately 70.7 and 75.9 map units. From this analysis, we presume that the doublet *Hin*dIII FG concerns hybridisation only to the G fragment, but that hybridisation occurs to both fragments of the *Bgl*II CD doublet. This point can be finally decided when a more complete analysis of the hybridisation patterns has been carried out. This provisional map summarising the maximum limits within which the hybridising regions lie is given diagrammatically in Fig. 2.

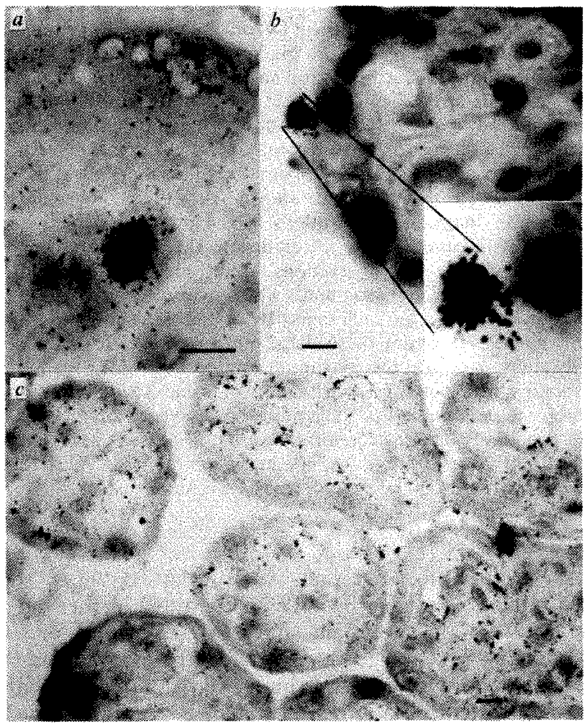

Fig. 3 Autoradiographs showing concentrations of Ad-2 complementary RNA in placenta. Ad-2 DNA labelled by the 'nick-translation' reaction with ^{3}H, was denatured and hybridised *in situ* to frozen sectioned human placenta in conditions that detect complementary cellular RNA[8–10]. *a*, A 'solitary' cell that shows a high concentration of label signifying a high concentration of Ad-2-related RNA. This cell type occurs relatively infrequently (about 2–3 per ×40 objective field) and occasionally seems to be loosely attached to the tissue (*b*). This may reflect the fact that it is a circulating cell. *c*, An example of a generally labelled area of placenta, after hybridisation as above. The grain distribution in this autoradiograph suggests that whole areas of this tissue contain Ad-2-related RNA at a lower level than the solitary, highly labelled, cells shown in *a* and *b*. Autoradiographic exposure 3 weeks. Controls of similarly hybridised λ phage DNA were negative. Scale bars, 10 μm.

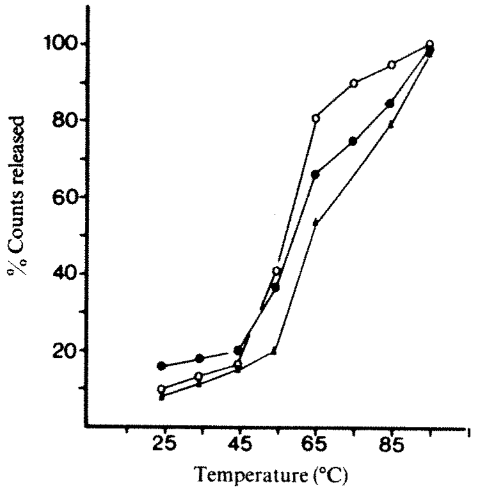

Fig. 4 Thermal dissociation of hybrids formed between human total ^{125}I-labelled RNA and human total DNA (○), and Ad-2 whole genomal DNA (●, sample 1; ▲, sample 2), from different sources. The curves show similar features, with both Ad-2 DNA samples having formed hybrids of rather higher thermal stability than total human DNA. Hybridisation conditions are described in the legend to Fig. 1. Dissociation was carried out by cutting spots of hybridised DNA from nitrocellulose filters of spot tests that had been shown to be positive by previous autoradiography on X-ray film as in Fig. 1. These were then counted by scintillation spectrometry in toluene-based scintillation fluid, washed and then treated in diethyl pyrocarbonate 0.1 in SSC (0.15 M NaCl, 0.015 M sodium citrate, *p*H 7.4) for 30 min, washed in SSC, and heated for 10 min in 1 ml 0.1 SSC and 0.1% SDS at each of the temperatures shown. The counts released were recovered from solution by trichloroacetic acid precipitation in the presence of 100 μg BSA per sample, dried by suction filtration and counted by scintillation spectrometry. Approximately 80% of the original radioactivity was recovered.

This provisional map has been confirmed with a further two independently obtained samples of Ad-2 DNA and with 10 separate samples of placentas, obtained from normal births, from two hospitals. We have also found the same pattern in the case of human adult liver RNA, and with liver, kidney, brain and spleen RNA obtained from a gorilla which died from the effects of minor surgery. The RNAs from four separate human cell lines maintained in permanent culture gave very faint patterns of hybridisation compared with the organ RNAs and are being studied in more detail. RNA obtained from chickens in the same manner as for other organs of primates did not hybridise in two separate tests.

That human organ RNA and other higher primate RNA contain sequences with homology to certain regions of the genome of Ad-2, but that such RNA apparently is relatively much less abundant in cell lines of human origin, indicated that the distribution of cells having such an abundance was not uniform. We investigated this aspect by hybridising ^{3}H nick-translated, denatured Ad-2 DNA to human placental cryostat sections *in situ* using a method which permits hybridisation to mRNAs[8–10]. After S_1 nuclease treatment and thermal rinsing to remove unhybridised probe or poorly matched hybrids, the preparations were autoradiographed and examined microscopically. Strong hybridisation occurred only to certain cells in the sections. These seemed to be solitary cells, with hybridisation to almost the entire area of the cell (Fig. 3*a*, *b*). Other areas of the sections showed a lower level of hybridisation which was, however, above the non-cellular background (Fig. 3*c*). There was no hybridisation in the case of λ phage ^{3}H-DNA hybridised in identical conditions. We presume from this that the bulk of the RNA that hybridised is contributed by a tissue cell subpopulation and that cells of this type are not among the cell lines that we examined.

Melting-temperature experiments

We carried out melting-temperature experiments to determine the thermal stability of the the hybrids formed on nitrocellulose between Ad-2 DNA and placental RNA. These were done by cutting out the relevant hybridised spots from the filter and heating them in solution at increasing temperature (see legend to Fig. 4) to measure the loss of hybridised RNA from the filters. Hybrids formed between human ^{125}I-labelled total RNA and two separate Ad-2 DNA samples and with total human DNA were compared. As can be seen from Fig. 4, the melts of Ad-2 hybrids showed similar characteristics and similar, though slightly higher, T_m values compared to the homologous hybrids, indicating that the hybrids to Ad-2 were reasonably thermally stable. This result was expected from the annealing conditions (legend to Fig. 1) which were quite stringent and essentially identical to those used in most published Ad-2 hybridisation studies (see discussion). We conclude that the hybrids that we detect between human RNA and Ad-2 DNA are at least as well matched as those in previous transcription studies of Ad-2. We are now investigating methods to determine the precise lengths of the hybridised regions. However, this is complicated by the fact that the organ RNA is to some extent degraded.

Immunological studies

Hybridisation between a viral DNA and human RNA from apparently uninfected tissues suggests similar protein coding functions in the sequences concerned. To test this hypothesis, rabbit cells infected with a clinical isolate of Ad-2 were used to raise antisera separately against the early-infected and late-infected cells (see legend to Fig. 5). The antisera were then reacted with six human cell lines (not shown) in an indirect immunofluorescence assay. All except one cell type, a human glioma (NG-118H) transformed by Rous sarcoma virus which was faintly positive, were completely negative. Controls of Ad-2-infected HEp 2 cells were brilliantly positive (Fig. 5*a*) as were transformed rat cells containing the extreme left-hand fragment of the Ad-2 genome[12] (not shown). Placental sections were also positive when treated with the anti-early antisera (Fig. 5*b*,*c*), but not with anti-late-infected cell antiserum. The fluorescence was concentrated on the surfaces of cells lining what seemed to be channels in the tissue as well as occurring diffusely in the cytoplasm of many areas. Some cells showed the nuclear fluorescence usually seen in transformed cells. However, this was rare and not intense. Of 10 placentas tested, 8 were undoubtedly positive in these tests and 2 were judged negative. We do not understand this variation, as all were positive in hybridisation tests for Ad-2-related RNA; however, it may be due to the fact that the antigens concerned are unstable and that the variations reflected the variable storage conditions of the tissues before we obtained them.

Antigens were then solubilised[24] from placental tissue and tested by gel diffusion in Ouchterlony plates against both early- and late-infected cell antisera, using controls of Ad-2-infected rabbit cell antigens (Fig. 6). There was no reaction with any dilution of uninfected cell antigens (not shown). Strong precipitin lines formed between the early-infected cell antisera and the antigens of both early- and late-infected cells, as expected, for both will contain the same early antigens, although presumably in different concentrations. Weaker but quite definite precipitin lines formed between this same antiserum and the wells containing placental antigens, and these showed partial identity with one of the lines originating from the early-infected cell antigen wells but no identity with late-infection antigens. The tests against anti-late-infected cell antisera were even more strongly positive against the infected cell antigens, particularly the late-infected cells. However, there were no visible precipitin lines between this antiserum and the wells containing placental antigens. Separate tests were then carried out in which a range of dilutions of the placental antigens were tested against each antiserum separately. No dilution used gave any precipitin lines with the late-infected cell antiserum (not shown). The early-infected cell antiserum, however, showed a single precipitin line that altered position between the antigen and antibody well depending on concentration. This shift is due to antigen–antibody concentration which affects the solubility and hence the mobility of the antigen–antibody complex. The fact that there was no precipitin line in the case of anti-late-infected cell antiserum suggests that the concentration of the relevant antibodies to early-infected cell antigens was very low.

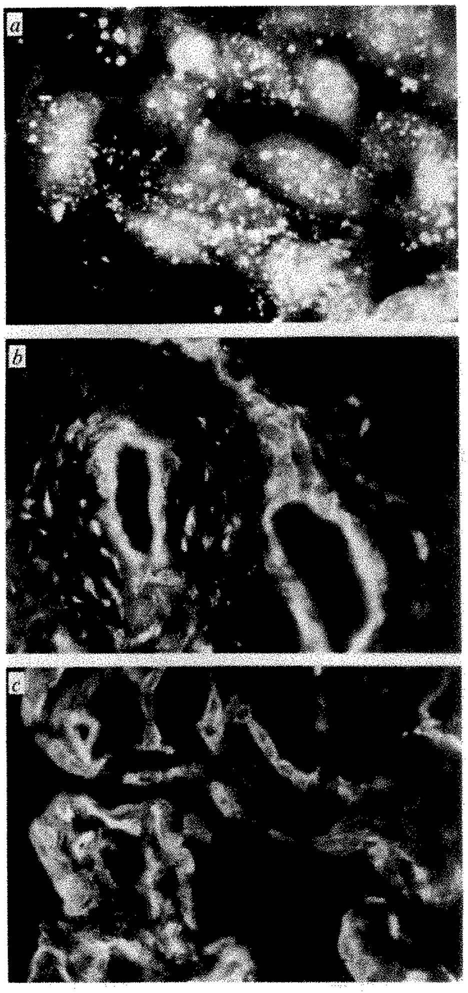

Fig. 5 Indirect immunofluorescence tests for antigens on: *a*, Ad-2 early-infected human cells (HEp 2); *b*, *c*, normal human placenta cryostat sections, using antiserum raised against Ad-2 early-infected rabbit cells (Rk-13), at a dilution of 1/40 and sheep anti-rabbit IgG conjugated with fluorescein isothiocyanate (Wellcome). The rabbit cells were grown in medium 199 supplemented with 2% rabbit serum and the antisera raised in rabbits. Cells were infected for 20 h in the presence of 20 μg ml^{-1} cytosine arabinoside. The resulting antiserum was negative for virus neutralising activity. Uninfected cell antiserum was also raised and was negative by immunofluorescence with these same subjects, and infected cell antiserum was negative with both uninfected HEp and RK-13 cells. The infecting adenovirus was obtained from a clinical isolate. Antiserum to late-infected cells was negative in similar tests. Fluorescence in the HEp cells is mainly on nuclear structures with some cytoplasmic fluorescence. Placental sections show stronger fluorescence in cytoplasmic regions, especially on what are apparently cells lining channels or vessels in the placenta, but nuclear fluorescence is also visible. These results, which demonstrate the presence of cross-reacting antigens between early-infected and apparently uninfected placenta, have also been obtained with all other tissues but not with cell lines tested (see text), and are confirmed by Ouchterlony gel diffusion (Fig. 6 and text).

We conclude from these preliminary immunological experiments that rabbit cells infected with Ad-2 contain certain antigens that are not present in uninfected rabbit, or human, cells in culture. We further conclude that some of the Ad-2-induced antigens are identical to tissue antigens present in most

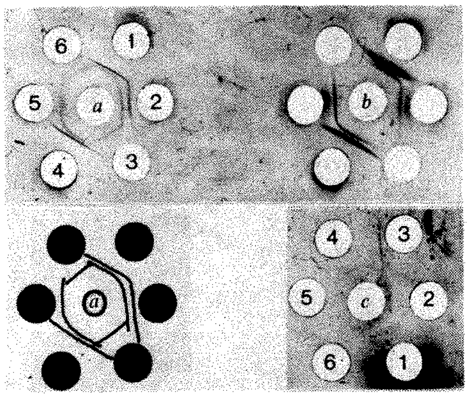

Fig. 6 Ouchterlony gels showing patterns of precipitation obtained between *a*, anti-early Ad-2-infected Rk-13 cells, and *b*, anti-late Ad-2-infected Rk-13 cell antisera. Wells are numbered 1–6 in the same manner in each case. Wells 1 and 4 contained dilutions of 1/50 and 1/100 of late Ad-2-infected antigens; 2 and 5 contained dilutions of 1/50 and 1/100 Ad-2 early infection antigens; 3 and 6 contained 1/50 and 1/100 dilutions of placental antigens. An interpretation of the pattern seen in *a* is shown below it. In *a*, precipitin lines can be seen between both wells containing placental antigens and the central well containing anti-Ad-2 early-infected Rk-13 cells. In 3 there is a suggestion of partial identity with one of the lines associated with well 2 as judged from the single spur. There are no lines visible between the central well and wells 3 and 6 in *b*, indicating absence from the late-infected cell of antigenic components related to those of normal placenta. Dilution experiments with this particular combination over the range of 1/10 to 1/1,000 of antigen concentration revealed no precipitation (not shown); however, a similar range of dilutions of the same combination in the case of *a* showed an arc of precipitation spiralling out from the centre well according to the dilution of antigen; this is shown in *c*, in which all wells contained placental antigen, as follows: (1) undiluted; (2) 1/10; (3) 1/50; (4) 1/100; (5) 1/1,000; (6) saline. These data confirm that normal human placentas express antigens that are associated with Ad-2 early infection as shown by immunofluorescence in Fig. 5.

human placenta samples, concerning mainly the early proteins of the adenovirus infectious cycle. Such antigens are not detectable on cell lines of human origin by immunofluorescence but were present in all tissues of gorilla (not shown). We are now attempting to characterise these antigens in more detail. The presence of antigens related to Ad-2 early function proteins in humans and in gorilla tissues correlates with the presence in these tissues of RNA molecules that hybridise with regions of the Ad-2 genome involved in coding early function proteins. We suppose from this that these RNAs code for the antigens that are shared between apparently normal human, and other primate, tissues. The *in situ* hybridisation result using Ad-2 DNA probes suggests that certain cells, or cells in a certain transitory state, which constitute a minor subpopulation in the placenta, contain a high concentration of the Ad-2-related RNA. The connection between this observation and the fact that the antigens concerned are rather ubiquitous in the tissues examined is unclear but is discussed below. However, as there are at least four regions of the Ad-2 genome that hybridise, it is possible that different cell types contain different proportions, or types, of the corresponding, homologous, RNAs, and consequently code for different antigenic moieties.

Discussion

The present findings are unique in the sense that there have been no previous reports of RNA sequences related to adenoviruses in apparently uninfected human cells. These findings are particularly intriguing as they relate to adenoviruses that are potent transforming viruses in animal hosts[3–6]. Moreover, the regions of homology include sequences in the extreme left-hand end of the Ad-2 genome that contains transforming genes of this virus. The consistency of the findings, there being no negative results in the 11 human tissue samples included in this study, indicates that the RNAs concerned may be ubiquitous in the population. Moreover, the presence of the same RNA molecules in gorilla is indicated from the similarity of the hybridisation patterns obtained with RNA from kidney, liver, spleen and brain. This suggests that the RNAs may also be common within the higher primate group, although more examples, involving some from a natural population, will be essential to support this.

Our criteria for hybridisation of the RNAs to Ad-2 DNA are those normally used in hybridisation mapping of Ad-2 (refs 25, 26) and are reasonably stringent taking the genome as a whole. Increasing the hybridisation temperature to 75°C reduced but did not prevent hybridisation. Moreover, the thermal stability of the Ad-2 DNA – human RNA hybrids seems representative of hybrids formed between human total DNA and the same human RNAs used in this work. We conclude from this that the hybrids are reasonably well matched. This is supported by the fact that there is demonstrable homology between the antigens coded during infection by Ad-2 and those present in human placenta and liver, and gorilla organs, which indicates similar coding functions of the RNA produced early in Ad-2 infection and that present in apparently normal higher primate organs.

These data, although consistent, are at present limited and the possible interpretations are, correspondingly, tentative. However, the findings are provocative and invite some speculations as to their significance. The RNAs concerned may have originated in either of two, not necessarily mutually exclusive, ways. Namely, host acquisition by an infectious process or the evolution of Ad-2 (and the C group adenoviruses) through the acquisition of nucleotide sequences similar to those found in the natural primate host.

The facts relevant to these interpretations are that only certain Ad-2 DNA regions are represented in human RNA. This tends to rule out a productive Ad-2 infection as the RNA source, as we would then expect to find RNA representative of the whole genome. Because all individuals investigated contained the RNAs in question, it is obvious that the mode of transmission is very efficient. This rules out a particular defective virus as the source unless we also assume that transmission is vertical and widespread. In this case, it is debatable whether such sequences belong to the host or to a virus. We cannot, however, exclude the possibility that the sequences we detect belong to a non-defective, incompletely Ad-2-related virus, in our view an unlikely explanation, or that Ad-2 DNA may be carried in the manner of Epstein–Barr virus[27], following infectious contact and subject to specific host transcriptional control.

The second hypothesis is that Ad-2 and related strains have evolved, or otherwise acquired, genes that are related to certain genes of their natural hosts. As it is known that Ad-5 can integrate with host DNA[28], such evolution seems likely. Also, RNA tumour viruses of chickens and mice contain sequences related to their host cells. In avian sarcoma viruses the transforming gene *src* is related in nucleotide sequence to the host gene *sarc*[13]. It is also known that the transforming region of a primate virus SV40, which is totally unrelated to Ad-2, is rather similar to Ad-2 in its transcriptional structure[29], although it is not known whether the proteins coded are functionally analogous. Such convergent evolution might reflect the fact that both viruses have acquired or evolved control elements concerned with the same host function, as both are primate viruses. Presumably, the advantage of such a mode of evolution would be that the virus would be better adapted to subvert host functions, for example, by using the host RNA splicing systems. Pressure to acquire control of the same system on the part of unrelated viruses could stem from the fact that the functions concerned are key elements in growth control. In this regard it is known that Ad-2 replicates in human cells significantly faster than Ad-12 (refs 30, 31), which does not, as far as we can detect, share the host-related nucleotide sequences.

Whether or not either hypothesis is wholly correct, our findings do indicate that human cells possess transcripts, from whatever source, closely related to DNA that maps within the transforming region of the adenovirus genome. This may be relevant not only to how the virus itself replicates and transforms, but also to how malignant human cells may alter their growth patterns. Moreover, at least four regions of homology are detectable which may mean that at least four different RNAs related to the viral DNA exist in human cells. In future studies these can be recovered and their corresponding genes cloned and identified. In the event that the second hypothesis is substantially correct, such genes may relate to important functions connected with cell and virus growth control. A search for similar sequences related to other DNA viruses is also suggested from the fact that antigenic similarity has been described between SV40-induced surface antigens and fetal antigens in hamsters[32].

The fact that Ad-2 early function antigens cross-react immunologically with apparently ubiquitous antigens present in the natural host, regardless of their origin, is likely to be medically significant. Bacterial pathogens that share antigens with human cells can precipitate autoimmune reactions, as in the rheumatic disease caused by *Streptococcus pyogenes* infections. Persistent adenovirus infections might therefore, by analogy, precipitate similar diseases. Thus, there might be a link between other rheumatic conditions or autoimmune diseases and the antigens that we detect. Of particular interest here is the identity of the cell type that seems to synthesise a high concentration of Ad-2-related RNA as determined by *in situ* hybridisation. If such synthesis implies a high content of related antigens, such a cell might be particularly at risk from an autoimmune reaction directed at these common antigens.

The cellular source of the cross-reacting antigens in placental tissue is unclear. By immunofluorescence, these antigens are widely distributed in the tissue. However, they do not appear on tissue-cultured cells of human origin. Moreover, the cell type that apparently possesses the greatest amount of Ad-2-related RNA as determined from *in situ* hybridisation, and thus is presumably most likely to synthesise most antigen, is relatively rare. One possible explanation is that different RNA molecules, related to different regions of the Ad-2 genome, are not equally abundant in all cells. Another is that the antigens or their precursors circulate in blood or other body fluids and/or that their distribution is altered as a result of post-mortem changes, such as blood clotting. Such a mechanism would partly explain why these antigens have not generally been found on cells in culture.

We thank Joe Bonventre and Ashley Dunn for samples of adenovirus type 2, Phil Gallimore for rat Ad-2-transformed cell lines and Ad-2 virus samples, Professor B. Marmion for discussions, Jeanette Muir for technical assistance, and Dr Bruce Hobson and staff at the Royal Infirmary, and the staff of the Elsie Ingles Hospital, Edinburgh, for providing placental samples. This work was supported by the Cancer Research Campaign and the Nuffield Foundation.

A jet associated with M89

AN optical jet, extending 10 arc min from the elliptical galaxy M89 (NGC4552) is reported here. Two low surface brightness shells partly surround the galaxy and a much fainter arc, 13 arc min away has also been detected. The jet was found on five deep plates of the Virgo cluster obtained by the 1.2-m UK Schmidt Telescope. Three sky-limited IIIaJ (bandpass 395–530 nm) and two IIIaF (630–685 nm) plates were taken on hypersensitised[1] emulsions. A slightly different plate centre was used for two of the plates.

The faintest objects on the plates were made visible by a contact copying process designed to detect very low surface brightness structures[2]. High contrast positives from the deepest IIIaJ plates were superimposed in register to reduce grain noise (Fig. 1). Low contrast detail, buried in the envelope of M89 was revealed by using an unsharp mask[3] to remove the large-scale density variations in the images. Objects smaller than ~1 arc min were unaffected by the mask and were further emphasised by the contrast enhancement process. Three of these high-contrast spatially-filtered positives were again superimposed in register. All the features clearly discernable on either kind of derivative made from at least two of the original plates (before superimposition) are sketched in Fig. 2, which is reproduced to the same scale as Fig. 1. A similar series of processes, using the same set of plates, was carried out on the superficially similar galaxy M84 (NGC4374). No unusual features were found.

All the derivatives from each of the plates clearly show a jet (A in Fig. 2) at a position angle of 115° extending 10 arc min (~36 kpc) from the nucleus of M89. The jet is brighter towards its tip but retains the same apparent width (~5 kpc) until it merges with the outer envelope of the main galaxy. The jet itself is slightly curved and contains some brighter condensations. One of these, (E) is off the axis of the jet and could be a background object. The outer envelope of the galaxy shows a distinct bulge on the eastern side, opposite the jet. To the south a sharply defined arc (B), reminiscent of a supernova remnant

0028–0836/79/0277–0279$01.00

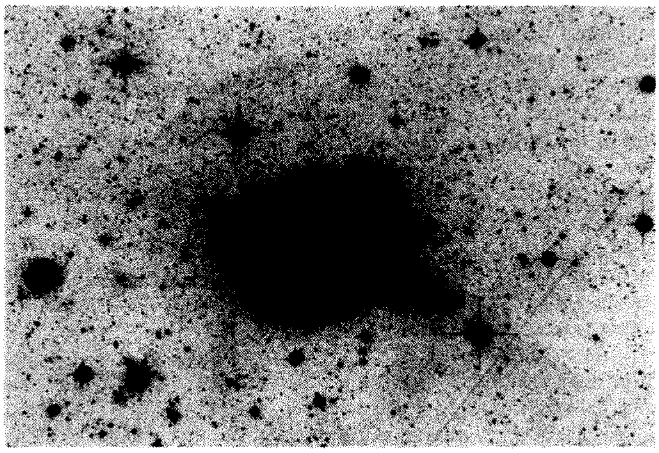

Fig. 1 Superimposed high contrast copies of two sky-limited IIIaJ plates showing the jet and three concentric shells. Same scale as Fig. 2.

shell, is visible, concentric with the nucleus of M89 and ~11 kpc long. The jet and southern arc are more obvious on the blue plates than on the red and are just visible on the originals. Diametrically opposite the southern bright rim and at a similar distance from the nucleus is a more diffuse arc (C) which appears as a circular patch on the red plates. The condensation D and extremely faint arc F, 47 kpc from the nucleus are evident only on the two deepest IIIaJ plates.

The dotted circle in Fig. 2 is the equivalent apparent radius of M89 at a (B) magnitude of 26.91 arc s^{-2} obtained from the photographic photometry of Fraser[4]. The circle is centred on the position of the optical nucleus.

In view of their low surface brightness, the nature of the jet and shells will be difficult to establish. Although the jet is of comparable brightness on the blue and red plates, suggesting that it is continuum emission, it could have a spectrum exhibiting [O III] 4959 and 5007 and Hα emission lines. This would be hard to reconcile with the known lack of interstellar gas in normal elliptical galaxies. Pure continuum could indicate synchrotron radiation, but no radio jet was found in observations by Heeschen[5]. The jet is therefore probably composed of stars. Tidal interaction with another galaxy cannot be discounted as the disruptive force but there seems to be no likely candidate in the vicinity and that mechanism would not account for the active radio nucleus or the concentric shells. The nucleus is a compact radio source, with a flat spectrum similar to that found in variable QSOs. The nucleus of M89 is variable at 6 cm (R. D. Ekers, unpublished data). The optical spectrum is unique among the limited number of active radio galaxies examined by Disney and Cromwell[6] in that it exhibits no emission lines. It seems likely that the jet and concentric shells are stars displaced by one or more violent outbursts in the active nucleus of the galaxy.

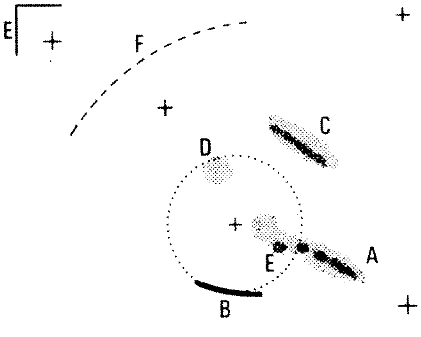

Fig. 2 Location of low contrast features visible in the spatial frequency-filtered derivatives of three IIIaJ plates.

I thank P. G. Murdin for useful comments and Drs J. Jones and R. D. Cannon for access to original plates.

Theory of the Earth-synchronous rotation of Venus

CARPENTER[1] noted in 1966 that the radar observations of the rotation period of Venus gave a figure remarkably close to one at which Venus would present the same aspect to the Earth at each inferior conjunction. Goldreich and Peale[2] discussed this as a possible resonance with a gravitational couple exerted by the Earth on a permanent transverse quadrupole moment of Venus, but noted that such a couple would be expected to be much smaller than that due to the Sun acting on the solid body tide. The rotation would continue to slow down due to tidal friction, and could not have been arrested in the resonance. We therefore proposed[3] that the solar couple on thermal atmospheric tides might be expected to apply an acceleration to the spin of Venus, thus opposing the body tidal frictional deceleration. (An effect in that sense occurs for the Earth.) The two opposed torques would have a different dependence on the rotation speed of Venus, and might balance at a particular value. As the rotation speed approached this value, the torque necessary for capture into a resonance would have become very small, and the effect exerted by the Earth might then be sufficient. A diurnal pressure wave of as little as 1 mbar could balance the body tide. Ingersoll and Dobrovolskis[4] have reconsidered this suggestion, and attempted a quantitative calculation of the atmospheric tide. Although their result seems to favour the theory, we show here that their approach is not valid. Ingersoll and Dobrovolskis consider a quasi-static atmosphere heated diurnally, and then calculate the mass distribution and hence the solar couple that results. But the quasi-static assumption is not justified for the known circumstances on Venus. Wind speeds must be expected[5], and have indeed been observed[6], that cause an advection of heat substantially faster than the motion of the subsolar point over the surface (~4 m s^{-1}); in these circumstances the atmospheric mass distribution will be determined by the dynamics of the convecting atmosphere. (The acceleration terms rather than temperature make the main contribution to horizontal variations of pressure and density.) A secure result cannot be obtained until the flow patterns and velocities are known, from a detailed theory of planetary convection, or from direct observation.

Some considerations can immediately be used to show that the dynamical effects are likely to be as strong or stronger than we showed to be needed for the resonance capture. First, wind speeds on Venus are fast relative to the planet's rotation rate, unlike the case for the Earth. The slow diurnal rotation (117 d) and the deep, radiation-absorbing atmosphere of Venus make it probable that most of the global convection pattern is relatively stationary with respect to the subsolar point, rather than being carried around with the planetary rotation as is the case for the Earth. Cloud pattern photography, for example, of the permanent disturbance downwind from the subsolar point, substantiates this, but is available as yet only for the upper atmosphere[7]. The atmospheric mass asymmetries created by this motion are subject to a continuous solar torque. Indeed they may help produce the high altitude 4-d circulation[8].

Second, the wind speeds of such an advection have been estimated by several authors[9], and speeds of the order of 5 m s^{-1} are expected in the densest levels of the atmosphere (above the surface boundary layer). On a slowly rotating planet, the dynamical pressure fluctuations associated with this, such as the pressure drop in a large eddy, are then of the order of ρv^2, where ρ is the density and v the wind speed. This suggests that variations of 15 mbar in the surface pressure are to be expected, a figure substantially larger than the minimum of 1 mbar that we showed to be adequate for the tidal stability of the resonant rotation.

Soviet measurements[6] with Veneras 9 and 10 found wind speeds of 40–50 m s^{-1} down to 30 km above the surface. The corresponding value for ρv^2 is ~180 mbar, and similar absolute values of the pressure fluctuations are then expected to occur down to the surface. These measurements, which generally confirm the calculations of Gierasch *et al.*[9], also indicated that wind speeds were similar over a substantial (~20°) range of longitudes[10], making it clear that they were associated with large-scale patterns rather than merely small-scale turbulence that would be inconsequential for tidal effects. The figure of 180 mbar is so much in excess of what is required that the distribution of the atmospheric mass assymetry can be very inefficiently organised and still be enough to stabilise the resonant rotation against solid body tidal drag.

We conclude that the dynamical effects of convection will give the Venus atmosphere asymmetries in its mass distribution with respect to the Sun that are fully expected to provide an adequate couple for the Earth-resonance theory. A more detailed discussion depends on an improved understanding of the entire atmospheric dynamics.

We thank Dr P. Gierasch for helpful discussions. This work was supported by NSF grants AST-17838-AO3 and AJM-76-81380.

Size of scallops and ripples formed by flowing water

THE passage of water over a soluble solid wall often gives rise to intersecting polygonal depressions or horseshoe-shaped pits known as scallops and flutes[1,2]. The geometry of these surface deformations is remarkably reproducible in given flow conditions, but there is no generally agreed theoretical framework for predicting their characteristic dimensions, such as the spacing between successive transverse ridges. I present here indirect evidence in support of the hypothesis that the scalloping of soluble surfaces is due to the imprint of eddy patterns inherent in turbulent flow near a passive wall, and argue that small ripples on a granular bed may be formed in essentially the same way.

The attribution of bedform morphology to the structure of wall turbulence, rather than to the physical properties of the bed itself, has been suggested several times[3–6]. We may call this basic assumption the wall-similarity hypothesis, since it implies by dimensional arguments referred to in the turbulence literature as the principle of wall similarity[7], that a characteristic length scale of the bedform should be a universal multiple of ν/u_*, where ν is the kinematic viscosity and u_* is the friction velocity. Although the wall-similarity hypothesis has been shown to account successfully for the size of scallops formed by dissolution both in geophysical flows[5] and in laboratory studies[6], its validity range is uncertain[1], and in particular no attempt has been made to apply it to features observed on granular beds. Among the diverse bedforms associated with non-cohesive sand, those described as ripples[8] resemble dissolution scallops most closely in size, and hence have the strongest claim to an explanation in terms of the wall-similarity hypothesis. However, it has been demonstrated experimentally[9,10] that ripple wavelength does not depend in a simple linear manner on ν/u_*, and this has been taken to mean that wall-similarity concepts are not relevant to sand beds[11].

Most of the literature on bedform morphology refers to flows occurring in nature or to laboratory simulations of geophysical flows, but several instances have been reported of flow-induced wall deformations in man-made industrial plant. A striking example is the formation (probably by a dissolution process) of

Fig. 1 Streamwise spacing of flow-induced surface deformations, λ, plotted against the wall-similarity parameter, ν/u_*. Chain-dotted line: $\lambda = 10^3\,\nu/u_*$. Broken lines inclined to the axes indicate the range of conditions covered by the original references.

0028-0836/79/0277—0281$01.00

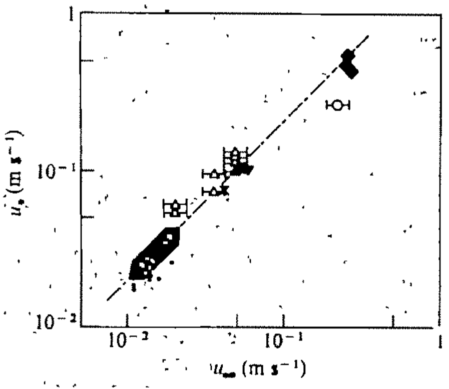

Fig. 2 Empirically determined friction velocity, u_*, for flow over naturally scalloped or rippled surfaces, plotted against the friction velocity, u_{*0}, calculated or measured for the same bulk flowrate over a smooth wall. For the key see Fig. 1. Chain-dotted line: $u_* = 2u_{*0}$.

rippled layers of magnetite on the internal surfaces of boiler tubes carrying hot water at a velocity of a few metres per second[12-18]. The morphology of the deposits is very like that of cave scallops or river-bed ripples, but the longitudinal wavelength is much smaller, of the order of 200–350 μm. Such a reduction of scale agrees well with wall-similarity predictions.

Several published accounts of wall deformations generated by flow are summarised in Fig. 1. The reported morphologies differ in detail, but all the deformations can be described as either scallops or ripples, displaying a definite transverse character and a well-defined average spacing, λ, in the direction of flow. Some of the original papers do not give sufficient information to permit exact calculation of ν/u_*. In these cases, plausible assumptions have been made regarding water temperature or Reynolds number, and where necessary u_* has been taken to be twice the friction velocity appropriate to a smooth wall at the same bulk flowrate, as calculated using the Moody chart[19] for pipe flows or by assuming a universal logarithmic velocity profile[7] for the flume and channel flows. This method of estimating u_* was based on an analysis of those sources giving information on the increase in resistance to flow accompanying the formation of scallops and ripples (Fig. 2).

The approximate proportionality apparent in Fig. 1 between λ and ν/u_* over a range exceeding four decades of length represents strong support for the wall-similarity hypothesis. Most of the data are fitted within a factor of two or three by the formula $\lambda = 10^3\,\nu/u_*$. Figure 1 includes some of my experimental points, obtained using a variety of granular beds, of order 1 mm thick, in a small laboratory flume. My results, considered in isolation, do not show the trend $\lambda \propto \nu/u_*$, but the group of points taken as a whole falls on the same line as data referring to the corrosive dissolution of steel[12-18], brass[20] and copper[21], the plastic shear of bitumen[22] and aluminium[23] and the rippling of colloidal-particle deposits in a water main[24,25]. On deeper sand beds[9], ripple wavelengths are larger by a factor of ~4 than those obtained in my tests, suggesting that the height attained by ripples, s, may influence their spacing; this idea is supported by the fact that as ripples develop from an initially plane bed, their wavelength increases until eventually stabilising as an equilibrium ripple height is reached[27]. Linear regression applied to the deep-bed data in the form $\lambda = A\nu/u_* + Bs$ yielded $A = 1{,}250$, in satisfactory agreement with my shallow-bed results, and $B = 13.3$, a value consistent with the commonplace visual observation that in the lee of a ripple crest there is an unsteady recirculation zone extending a distance of the order of $10s$ downstream. However, allowance for ripple height does not adequately account for the anomalously large spacing of river-ice ripples[26], and it is possible that additional corrections to the basic wall-similarity estimate, as yet unidentified, will prove necessary for the accurate prediction of λ.

As there is no systematic divergence in Fig. 1 between data points relating to the rippling of granular beds or plastically deformable surfaces and points referring to dissolution processes, it seems that the applicability of the wall-similarity hypothesis is not limited to dissolution scallops alone. The evidence suggests the size of both scallops and ripples is determined primarily by the scale of pre-existing eddies in the adjacent turbulent flow. If circumstances permit the surface deformations to become so pronounced that extensive regions of separated flow are set up behind crests, the morphology and characteristic dimensions of the deformations will in general be modified, but it seems that this should properly be regarded as a secondary complication. Flow separation may perhaps be best considered as responsible merely for furnishing final sculptural details, determining, for example, whether scallops are formed rather than ripples, while the overall scale of the bedform has its origin in eddy patterns already present in the flow before surface irregularities have become sufficiently marked to induce separation. (These remarks do not, of course, apply to large-scale bedforms such as dunes or antidunes.)

If this perspective is accepted, the fact that the wavelength of ripples on a granular bed does not vary directly with ν/u_* is no longer irreconcilable with wall-similarity ideas. Suppose, for example, that the amount by which u_* exceeds the threshold of movement is a factor affecting bedform length scale, possibly through its influence on ripple profile and hence on the extent of the separation zone in the lee of a crest. Such a second-order effect, although subsidiary in the sense that it operates in the context of a bedform whose characteristic dimensions are fixed principally by turbulence length scales may, nevertheless, mask the simple linear dependence of λ on ν/u_* when the latter quantity is varied over the necessarily restricted range available in flume experiments, where u_* is bounded below by the threshold of movement and above by the necessity of preventing the ripples giving way to a different bedform regime.

The wall-similarity hypothesis for the rippling of granular beds may also provide an explanation for the absence of ripples when grains are larger than a critical size. For grain Reynolds numbers which are not too small, the Shields criterion is[8] $u_{*0} = 0.2(\Delta\rho g d/\rho)^{1/2}$ where u_{*0} is the friction velocity at the threshold of movement, ρ is the water density, $\Delta\rho$ is the difference in density between particle and fluid, d is the particle diameter and g is the gravitational acceleration. The maximum observable ripple wavelength for a bed of grain size d is therefore

$$\lambda_{max} = 1{,}000\,\nu/u_{*0} = 5{,}000\,\nu(\Delta\rho g d/\rho)^{-1/2}$$

But as the height of a fully developed ripple is usually no more than a tenth of its wavelength, a ripple will be indistinguishable from background bed roughness unless $\lambda_{max} > 20d$, say. Hence the grain size above which rippling would not be observed may be estimated as

$$d_{max} = (250\nu)^{2/3}(\Delta\rho g/\rho)^{-1/3}$$

Inserting physical properties appropriate to sand and water at ambient temperatures, the predicted d_{max} is 1.6 mm, which compares favourably with the value of about 0.7 mm found empirically[11].

Although no mechanistic explanation can be given for the value of the constant of proportionality between λ and ν/u_*, its order of magnitude suggests that the eddies responsible for the formation of scallops and ripples may be identified with the coherent flow structures known as sublayer bursts[28,29]. The dynamics of sublayer bursts are not understood, but empirical studies of turbulent flow over a smooth wall have established that they are elongated in the streamwise direction, with a typical lateral spacing[30-33] of 100 ν/u_* and a longitudinal length scale[29] in the approximate range 1,000–1,500 ν/u_*. Relatively few experiments have been performed to examine how the behaviour of sublayer bursts is modified by surface roughness[34,35], but in the case of a wall roughened by transverse ribs the streaky structures associated with bursts have been observed in the regions between ribs[34]. The bursts, which near a smooth surface occur randomly in position and time, possibly become locked into the irregularities of a deforming wall, thereby imposing bedform dimensions which reflect their own characteristic longitudinal scale, approximately $10^3\ \nu/u_*$. This speculation receives some support from evidence that bursts can impose their lateral length scale when longitudinal grooves are formed on a soluble[2] or erodible[35,36] wall. It is also interesting that as the flowrate is varied over a wall into which artificial ripples have been machined[37], the resistance to flow passes through a maximum when the ratio between ripple spacing and ν/u_* is $\sim 10^3$ (Fig. 1). Such a resonance phenomenon is consistent with the postulated tendency of sublayer bursts to lock into a spatially periodic pattern of transverse ridges: at resonance the surface morphology can be envisaged as giving the maximum possible assistance to the bursts in projecting low-momentum fluid towards the core of the flow, augmenting the Reynolds stress.

Iron–nickel 50–50 superstructure in the Santa Catharina meteorite

MÖSSBAUER effect and X-ray diffraction measurements have shown that thin lamellae of the Cape York and Toluca meteorites contain the ordered phase Fe–Ni (50–50%) with the structure L10 (refs 1–3). The bulk of these meteorites consists mainly of body centred cubic (b.c.c.) iron–nickel α-phase alloy. We report here Mössbauer spectra, electron microprobes and X-ray measurements which show that in contrast to this, the bulk of the Ni-rich ($\sim$35%) Santa Catharina Ataxite consists of up to 50% Fe–Ni superstructure[4].

Thin slices of the bulk of the Santa Catharina meteorite from specimens of the collection from the Museu Nacional in Rio de Janeiro were cut with a precision saw, carefully avoiding thermal stresses in the sample. Absorbers for Mössbauer spectra measurements were prepared by polishing the slices to a thickness around 70 μm. The spectra were recorded with a 20 mC source ^{57}Co in Rh matrix with a velocity drive coupled to a multichannel analyser of 1,024 channels. A 370/145 IBM computer was used for folding and analysing the data with a lorentzian least square fitting.

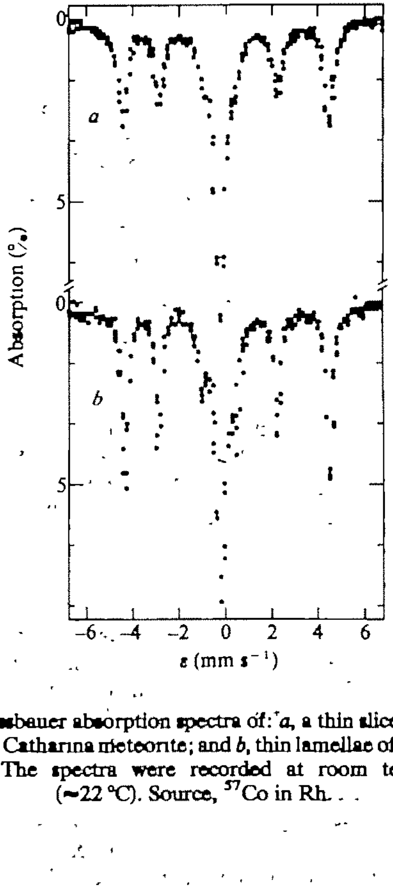

Fig. 1 Mössbauer absorption spectra of: *a*, a thin slice ($\sim$70 μm) of the Santa Catharina meteorite; and *b*, thin lamellae of the Toluca meteorite. The spectra were recorded at room temperature ($\sim$22 °C). Source, ^{57}Co in Rh.

Figure 1 compares a spectrum of the Santa Catharina sample with one obtained in the same conditions with a thin lamella of the Toluca meteorite, in which X-ray determinations showed the presence of the superstructure[3]. Both spectra are a superposition of two spectra: (1) a central line from a paramagnetic phase; and (2) an asymmetric 6-line spectrum, due to the L10 superstructure, which gives rise to a quadrupole splitting caused by the non-cubic surroundings of the iron atoms in this alloy[5–7]. The magnetic hyperfine field H_i and the electric quadrupole shift ε of the Santa Catharina sample are about the same as those observed with the lamella (lamella: $H_i = 289 \pm 2$ kG, $\varepsilon = 0.20 \pm 0.02$ mm s^{-1}; Santa Catharina: $H_i = 291 \pm 3$ kG, $\varepsilon = 0.17 \pm 0.02$ mm s^{-1}). The linewidths obtained with the Santa Catharina ($\Gamma \sim 0.52$ mm s^{-1}) are larger than those obtained with the Toluca lamella ($\Gamma \sim 0.32$ mm s^{-1}). This may be due to the larger thickness of the sample. Only minor changes, both in the paramagnetic central line and in the magnetically split Mössbauer spectrum, were observed on going from room temperature to liquid nitrogen (77 K) and liquid helium (4.2 K) temperatures. This surprising result, will be discussed in detail elsewhere.

As has been observed with the Cape York lamellae[2], the Mössbauer spectra of samples from the Santa Catharina meteorite at 732 K show that the breakdown of the superstructure occurs over a time scale of $\sim$10 h.

0028–0836/79/0277—0283$01.00

From our results, the area ratio of the 6-line spectrum to the single line, we conclude that ~50% of the Santa Catharina meteorite consists of the ordered Fe–Ni alloy with L10 structure. In the limits of sensitivity of the Mössbauer effect no evidence was found for other iron-containing minerals.

Electron microprobe (Microscan 5, Cambridge Scientific Instruments) analysis of the polished Santa Catharina samples indicates clearly the presence of at least two phases[8] as shown in Fig. 2. Microanalysis at points of the two phases indicate, from an average of 50 determinations, that the darker phase has a homogeneous composition, 51–50% (by weight) of Ni and 49–48% of Fe and that the lighter phase has a more heterogeneous composition containing nearly 27% of Ni. The meteorite consists of an intergrowth of orientated domains of these two phases, which implies that slices cut from the meteorite will always contain both phases. The presence of oxygen and sulphur in maximum amounts of 1–2% were found uniquely on the Ni-rich phase. Larger proportions of oxygen have been reported in this phase from earlier microprobe work[9]. The discrepancy may be due to the fact that earlier measurements were made on a severely oxidised sample. The fact that our samples taken from the bulk of the Santa Catharina meteorite show only traces of corrosion demonstrates that care has to be taken when results from different specimens of the Santa Catharina meteorite are compared[10]. We have also studied the sample from Santa Catharina by X-ray techniques. Oscillating crystal photographs show that the sample over areas of at least 1 mm^2 is essentially a single crystal, and that it contains the superstructure L10 of Fe–Ni. The X-ray photographs showed no traces of martensitic α_2 phase.

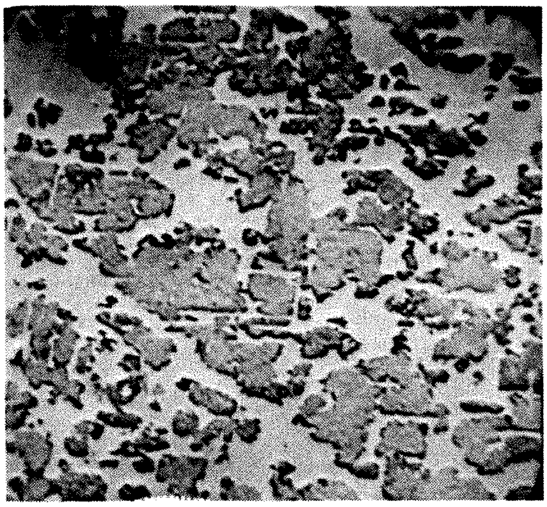

Fig. 2 Back-scatter electron image from electron microprobe analysis of a polished surface of the Santa Catharina sample. From point analysis determination it is found that the dark areas correspond to the Fe–Ni ordered phase whereas the light ones correspond to the Fe-rich paramagnetic phase.

Remarkably ~50% of the Santa Catharina meteorite, which originally may have been a 25,000 kg meteorite[11], consists of the ordered Fe–Ni structure. This structure has only been obtained by strong neutron or electron irradiation of disordered alloys at temperatures near the ordering temperature[5–7] ($T_c \approx 320$ °C). Diffusion processes substantially below T_c are too slow to obtain thermodynamic equilibrium[12]. The presence of the ordered Fe–Ni in Santa Catharina and other meteorites[1–3] is probably due to the slow cooling of the meteorite parent body.

Further experiments are in progress to clarify the nature of the iron-rich paramagnetic phase as well as the magnetic properties of the ordered Fe–Ni phase.

Microprobe analysis were performed by H. Schorscher, C. Wiedmann, and C. Jehanno.

Paraffinic hydrocarbons from supercritical-gas extracts of coal as organic geochemical markers

PARAFFINIC hydrocarbons have been proposed as indicators of the conditions obtaining during the deposition and subsequent maturation of sediments[1–4]. We consider here the relationship between the rank (as measured by carbon content) of coals and analytical results for the alkane fractions obtained by a novel extraction procedure (under investigation for the derivation of liquid fuels and feedstocks from coal[5,6]) which uses super-critical gases (SCG). We first discuss the limitations of *n*-alkane distributions and then deal with acyclic isoprenoids, drawing particular attention to the ratio of pristane to phytane.

In the *n*-alkane fractions of coals, like those from some other sediments, odd carbon numbers predominate over even[3]. For a series of Saar coals the carbon-preference index (CPI) varied systematically from 1.59 to 1.00 with degree of coalification[7], and a related parameter dropped[8] from 15.3 to ~1.0 for Australian coals as the carbon content changed from 67% to over 90%. On the other hand, the CPI of *n*-alkanes from hatchettites (coal-associated minerals) varied only between 0.96 and 1.06 (ref. 9). Recently, White *et al.* have questioned the correlation between *n*-alkane distributions and coal rank for paraffins from coal hydrogenated in the SYNTHOIL process[10].

We have isolated paraffinic hydrocarbons from a variety of coal derivatives by silica-gel chromatography of the portion soluble in *n*-pentane. Gas chromatographic analyses were then made on both packed and capillary columns for whole alkane fractions and for the straight-chain and branched-plus-cyclic alkane fractions separated on a molecular sieve[11–13]; mass spectrometry enabled unambiguous identification of individual alkanes[12]. Table 1 and Fig. 1 present our results for the distributions of *n*-alkanes derived from SCG and Soxhlet extraction, and low-temperature carbonisation from UK, Turkish and

¶ Based on 10% tar yield[26].

US coals, together with Kershaw's data for extracts of a South African coal[14]. By volatilising liquids otherwise insufficiently volatile to distil at the temperatures used, the SCG extraction process[5,6] yields much greater amounts of paraffins than conventional extraction procedures, but without appreciable hydrogen transfer[11].

The low C_{10}–C_{15} *n*-alkane contents in Fig. 1*a*, *c*, *d*, and *g* provide some evidence that the alkane fractions are not significantly degraded during SCG extraction over brief periods at around 340 °C. Indeed, although SCG extraction at 350 °C of the Markham Main (UK) and Sigma (South African) coals produces much greater quantities of *n*-alkanes than the mild Soxhlet extraction process (Table 1), the *n*-alkane range is almost identical (compare Fig. 1*d* with *f*, and *g* with *i*). The virtual absence (<0.01%) of alkenes in low-temperature SCG extracts (Table 1) also suggests a very low degree of pyrolysis. On the other hand, alkanes from a tar generated by fluidised-bed carbonisation[15] of Markham Main coal showed a roughly gaussian distribution (Fig. 1*h*), with a shift to lower carbon number compared with SCG extraction (Fig. 1*g*); significant quantities of alkenes detected in this and other low-temperature tars (Table 1) are thought to arise by de-methanation and de-ethanation of *n*-alkanes. Moreover, even SCG extraction at only 400 °C generated alkenes from Turkish lignites, and shifted the *n*-alkane distribution from that of a 340 °C extract (compare 1*a* with 1*b*); the CPI fell from 1.47 to 1.16 (Table 1). Alkenes were also apparently present in the 400 °C SCG extract of Daw Mill coal[13]. CPI values for the *n*-alkanes derived from Kershaw's data[14] also illustrate the effect of increasing the SCG extraction temperature from 350 °C (CPI 1.33) to 450 °C (CPI 1.01). Other SCG extracts at 400 °C, as well as low-temperature tars, exhibit CPI values near unity (Table 1).

Because it yields much larger quantities (by up to two orders of magnitude) of paraffins, SCG extraction without pronounced cracking, should provide alkanes that are more representative of the whole coal than does simple extraction (which yields only 0.007–0.099%, in refs 8, 10 and 14 and this work). Now, two sources of alkanes in coals must be considered: (1) the material physically absorbed in the micropore structure[16]; and (2) the compounds generated by chemical breakdown of oxygen-containing compounds, or long alkyl chains, shown[13] by ^{13}C NMR to be bonded within the coal matrix.

Vahrman attributed the increasingly smooth carbon-number distribution of *n*-alkanes from coal as extraction times become more extended to the differences in accessibility of the *n*-alkanes with high CPI (from the leaves, cuticle, and so on of the plants from which the coal is derived) as compared with those of lower CPI (originating from heartwood)[16]. A similar effect is evident when one compares CPI 1.27 for Soxhlet extraction (benzene–ethanol gave better yields than toluene) with CPI 1.09 for SCG extraction at 350 °C of the Markham Main (UK) coal; for the South African coal, the CPI decreases from 1.93 to 1.33 for analogous extracts. However, Allan *et al.* have shown that moderate temperature increases (from 275 to 375 °C for 24 h) can substantially change *n*-alkane distributions from UK vitrinites[17]. Evidently the extra alkanes generated on heating vitrinites have a different degree of odd/even predominance from those accessible to Soxhlet extraction; thus one cannot distinguish between the two processes, (1) and (2) above, as to the source of the extra *n*-alkanes in the SCG extracts. On the other hand, coal hydrogenation procedures, such as the SYNTHOIL process[10] and hydrogen-assisted SCG extraction (Table 1), clearly yield even larger quantities of *n*-alkanes, probably by hydro-cracking of aliphatic side chains.

Thus, apparent correlations between CPI and coal rank are almost certainly spurious because they are based on atypical proportions of *n*-alkanes obtained by simple extraction; furthermore, CPI values for *n*-alkanes derived by processes involving heating above 350 °C, or by hydrogenation, are also unreliable. SCG extraction at 340–350 °C may yield more representative samples, but the variety of origins of the alkanes extracted in this way renders the CPI of doubtful value in correlations with coal rank: CPI values for four coals from diverse sources show only a very approximate correlation with dry-ash-free carbon content (Table 1). All that can be said is that the large concentrations of C_{23} and higher *n*-alkanes are consistent with the predominantly land-derived nature of each sediment; a marine origin is typified by lower chain lengths[1,2] (Fig. 1).

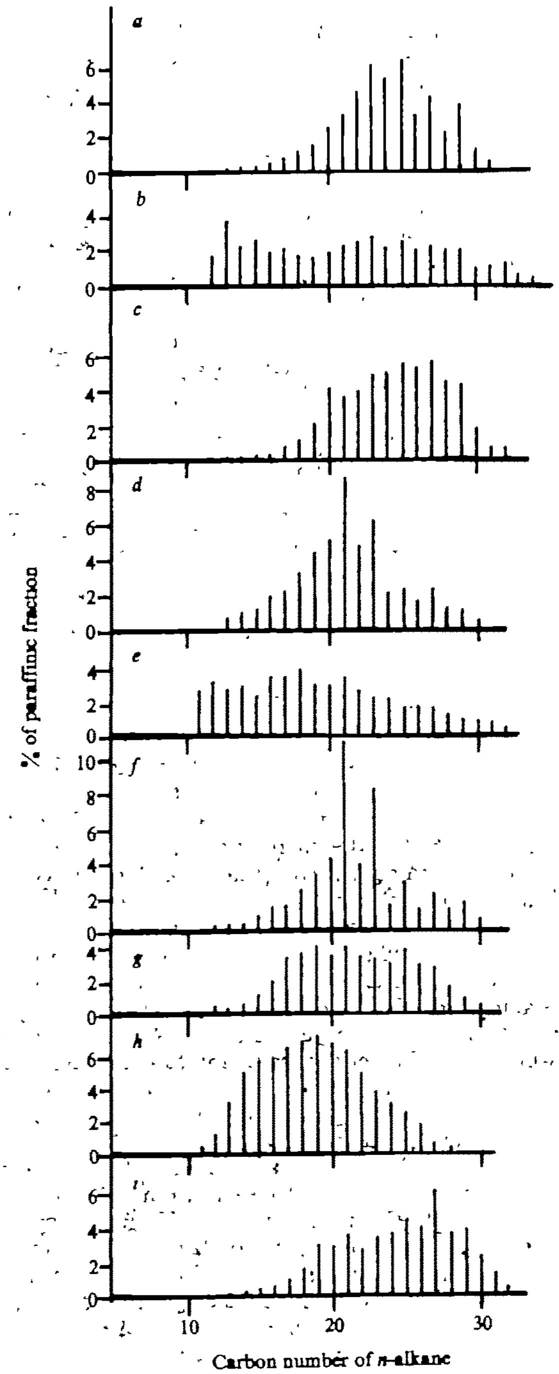

Fig. 1 Distributions of *n*-alkanes in paraffinic fractions of coals: *a*, Turkish lignite 1 (Elbistan), SCG extraction[27] at 340 °C; *b*, Turkish lignite 1, SCG extraction at 400 °C; *c*, Turkish lignite 2 (Seyitomer), SCG extraction[27] at 340 °C; *d*, Sigma (South African) coal, SCG extraction at 350 °C; *e*, Sigma (South African) coal, SCG extraction at 450 °C; *f*, Sigma (South African) coal, Soxhlet extraction with 3:1 chloroform/methanol for 100 h; *g*, Markham Main (UK) coal, SCG extraction at 350 °C; *h*, Markham Main (UK) coal, fluidised-bed carbonisation at 430 °C; *i*, Markham Main (UK) coal, Soxhlet extraction with 7:3 benzene/ethanol for 50 h. (*d*), (*e*) and (*f*) from ref. 14.

Acyclic isoprenoids may provide clearer evidence than *n*-alkanes of the geochemical history of sediments[2] as their major precursor is thought to be the phytyl side chain of the chlorophyll pigment from the original plant material. The presence of six derived hydrocarbons (C_{14}, C_{15}, C_{16}, C_{18}, C_{19} and C_{20} isoprenoids) has been demonstrated in numerous coal extracts and tars[3]. In Australian sub-bituminous coals[18], the pristane (C_{19}) content of the alkane fraction of (low-percentage) chloroform–methanol extracts begins to increase as carbon contents exceed 76%, but the phytane (C_{20}) concentration does not increase significantly until much later in the diagenetic process, corresponding to 83–85% carbon. At this stage the pristane/phytane ratio (Pr/Ph) is a maximum[18]. Parallel relations have been demonstrated between Pr/Ph and reflectance of New Zealand vitrinites[19], and with the maturity of shales from the Douala Basin[20]. The inter-relation of coal maturation and oil formation[18,21] is emphasised by correspondence between Pr/Ph for oils and the rank of coals in associated beds[22]. These changes during maturation, however, may not entirely erase the partial record of the palaeoenvironmental conditions during sedimentation provided by Pr/Ph[2]; by increasing the relative proportion of pristane to phytane, thermal diagenesis preserves Pr/Ph ratios greater than one, typical of deposition in oxic conditions[2,22].

In contrast with the CPI of *n*-alkanes, and in spite of the threefold increase in the quantity of isoprenoids liberated during SCG extraction, Pr/Ph ratios are similar for SCG and Soxhlet extracts and, even for low-temperature tars, from the same coal (Table 1). Moreover, even though the coals are of diverse origin, the Pr/Ph ratios still fit fairly closely to the curve for simple extracts determined for Australian coals by Brooks *et al.*[18]. The consistency of the Pr/Ph ratio in differing extraction conditions, and the similarity in thermal stabilities of isoprenoids reflected in the agreement for low-temperature tars, clearly make this parameter useful in discussing the geochemical history of coals, although more than one origin is possible for these compounds.

The isoprenoids form a higher proportion of the total paraffins from Soxhlet extracts than from SCG extracts, in keeping with Vahrman's suggestion[16] that branched alkanes are more accessible within the micropore structure. However, as for *n*-alkanes, the release of isoprenoids bonded within the coal structure must also be taken into account; Connan has shown[19] how larger quantities of pristane and phytane were extractable from lignite after heating for 3 days at 300 °C.

The completeness of extraction of isoprenoids by the SCG method is indicated by the similarity of the total contents (expressed as a fraction of the original coal) in products obtained at 350 °C and in the presence of hydrogen at 400 °C (Table 1). Indeed, for the Markham Main coal, isoprenoid content (with pristane predominant at as much as 300 p.p.m.) suggests that much of the chlorophyll-derived phytol remains in 'fossil' form. The biochemistry of Palaeozoic flora is obscure; modern descendants of such plants may differ markedly in their environments and occupy different ecological niches[23]. However, if a chlorophyll content[24] of 0.7–1.3% (dry basis) for higher plants including ferns and mosses is taken as appropriate, the total available phytol would then amount to between 2,000 and 4,000 p.p.m. of this, compared with 500 p.p.m. derived isoprenoids in the coal.

In conclusion, SCG extraction at about 350 °C causes little thermolysis and is favourable for extracting relatively large quantities of paraffins representative of the original coals. Because of the different nature of *n*-alkanes physically absorbed in the coal, and at least partly accessible to Soxhlet extraction, as compared with those chemically released by heating, the CPI is inappropriate for monitoring deposition and maturation. The isoprenoidal hydrocarbons, and especially the Pr/Ph ratio, are more widely applicable as geochemical markers, and valuable for commercial products derived from coal by newer liquefaction processes.

We thank Rexco and the FMC Corporation for samples of their tars, and the National Coal Board for permission to publish this paper; however, the views expressed are those of the authors. Financial support from the British Council, the European Coal and Steel Community, and from NATO is also acknowledged.

Steroids ketones in surface sediments from the south-west African shelf

STEROIDS are a class of biologically produced compounds which may serve as tracers for the transformation processes of labile organic matter in sediments. Diagenetic alteration of steroid alcohols (sterols) by geochemical and biological processes often leads to the accumulation of transformed products in the sediments. By elucidating these structures and determining their concentrations we should be able to determine their reaction mechanisms and rates of degradation. We have previously postulated that steroid ketones (stanones) are intermediates in the diagenesis of sterols to sterenes, a group of unsaturated steroids detected in some marine sediments[1] (Fig. 1). We report here the isolation, identification, and geochemical significance of a series of 4-methyl stanones and their 4-desmethyl counterparts from anoxic surface sediments in an upwelling zone on the south-west Africanshelf, Walvis Bay, RSA. To our knowledge, this is the first report of stanones being observed in Recent marine sediments, although 4α-methyl stanones have been reported previously as major components of the immature Messel oil shale[2].

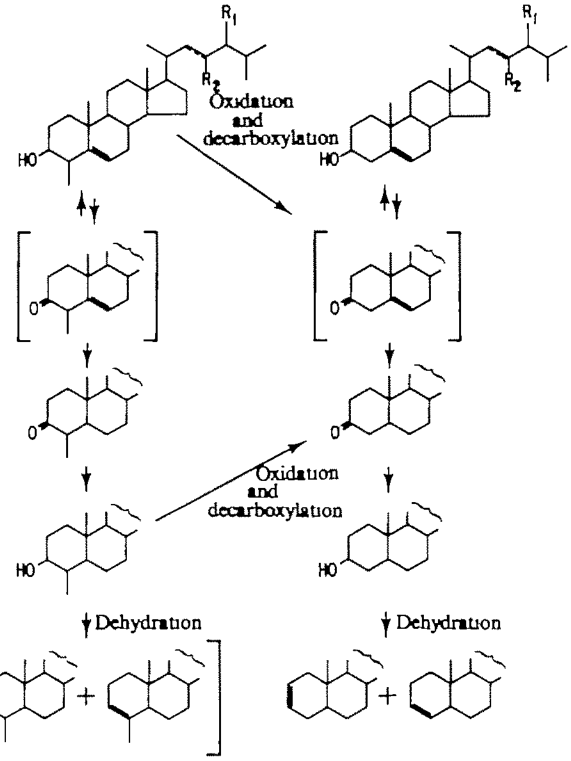

Fig. 1 A proposed mechanistic pathway for the microbiological or chemically mediated degradation in sediments of stenols to sterenes through stanone intermediates. Compounds in parenthesis are intermediates not isolated in this study.

Sediment samples were collected on RV Atlantis II Cruise 93, Leg 3, Capetown to Capetown, RSA in December 1975–January 1976. Core 16, taken from Station 11 at a water depth of 49 m at 22°47.5′ S, 14°25.8′ E, was analysed for its sterol (stenol + stanol), stanone, and sterene contents. The geology of this area has been described by Bremner[4,5] and the advantages of doing organic geochemical research in Walvis Bay by Boon *et al.*[6,7] and Morris and Calvert[8]. The sediment analysed was an organic-rich diatomaceous mud, composed mainly of frustules of *Coscinodiscus*, *Actinocyclus*, and *Thalassionema*. The top 4 cm of sediment were treated with 3 M HCl to remove the large amount of carbonate and Soxhlet extracted with benzene–methanol as previously described[3]. Column chromatography of this extract was performed on a 5% deactivated silica gel column using increasing amounts of ethyl acetate in hexane as eluant[3]. Fraction 1, eluted with hexane, contained various alkanes, cycloakanes, alkenes, cycloalkenes, and sterenes. Fraction 6, eluted with 15% ethyl acetate in hexane, contained the steroid ketones. Androstane was added as an internal standard. Blanks were also analysed during the extraction, isolation and analysis and contained negligible concentrations of stanones in the samples. 5α-Cholestan-3-one was added to pre-extracted sediment in the extraction thimble and used to quantify stanone recoveries. Mass spectra were obtained using a Varian aerograph 1400 gas chromatograph equipped with an SE-52 glass capillary column (25 m × 0.30 mm i.d.) interfaced to a Finnigan 1015 C quadrupole mass spectrometer[1]. The mass spectrometer

is interfaced with a Systems Industries 150 data system with DEC PDP 8-E (8K core) computer. The carrier gas (He) flow rate was 2–3 ml min^{-1}, the injector temperature was 250 °C, and the column was programmed from 70 to 260 °C at a rate of 4 °C min^{-1}. A more detailed description of the analytical methodology will be published elsewhere.

Four series of stanones were identified (Fig. 2) which differed primarily in (1) unsaturation at the C-22 position; (2) methylation at C-4; and (3) alkylation at C-24. 4,23,24-Trimethylcholest-22-en-3-one or 4-methyl-24-ethylcholest-22-en-3-one (XII) and 4,23,24-trimethylcholestan-3-one or 4-methyl-24-ethylcholestan-3-one (VI) were the major components, found in concentrations of 2.5 μg per g and 1.0 μg per g dry weight sediment, respectively. These structural identifications are based on published mass spectra and fragmentation patterns of other stanones[9–12]. However, as the mass spectrum of the 4,23,24-trimethyl compound is essentially the same as that of its 4-methyl-24-ethyl isomer, a definitive structure proof will have to await further separation and NMR studies[9]. Other stanones were detected at concentrations ranging from 3 to 16% of (XII), with the exception of (IV) and (X) which were found in concentrations of <1%. Structural elucidation of the stanones was based on relative retention times on high resolution glass capillary gas chromatography and comparison of GC–MS spectra with published mass spectra[11–17] or mass spectra obtained from authentic standards (I and IX). Mass spectral fragmentation of the Δ22 unsaturated stanones was dominated by ions corresponding to cleavage of the side chain, bonds C-17–C-20 and C-20–C-22 (Fig. 3*a*)[10,17]. The major fragments of the saturated stanones arose from cleavage of ring D (Fig. 3*b*)[11]. In addition, both the 5α and 5β isomers of (I) and (II) were detected, the 5β having an intense M-70 fragment[12]. The carbonyl group in the three position has little effect on the fragmentation patterns of these compounds due to the influence of the C-17 side chain[17]. The stereochemistry of the methyl groups at C-4 and C-24 is unknown, although the 4α steroids are the dominant form found in nature[18]. On the other hand, 4β steranes have been found in oil shales[19]. No stanones unsaturated in the ring system were detected, nor were any 4,4-dimethyl stanones identified, although it seems from mass spectral evidence that some of these gem dimethyl compounds may be present at very low concentrations. The mono- and di-unsaturated 4-desmethyl sterenes[1] of both the saturated and unsaturated Δ22 series were detected and correspond to their side chain alkyl-substituted 4-desmethyl stanone counterparts.

The occurrence of 3-ketosteroids in biological systems is limited. 4α-Methyl-3-ketosteroids are known to be intermediates in sterol biosynthesis, but are only detectable in trace concentrations[20,21]. Hence, a planktonic or benthic faunal or floral source for sedimentary stanones is unlikely, although few studies have been undertaken in the marine environment[21]. It has been proposed that stanones are possible intermediates in one transformation pathway for the reduction of stenols to stanols in sediments[1,22]. The 4-desmethyl stanones isolated from surface sediments in Walvis Bay structurally correspond to their stenol precursors detected in these sediments (C. Lee, unpublished results) and in the overlying water column (R.B.G., unpublished results). Thus these stanones may represent a series of stenol oxidation products.

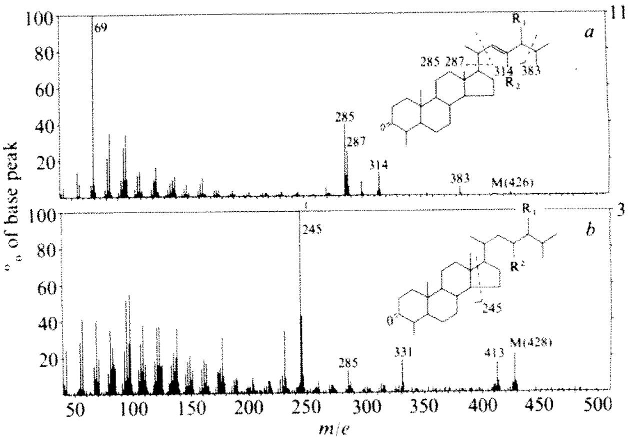

Fig. 3 Mass spectral line diagrams as obtained by glass capillary GC–MS of stanone fraction of core 16: *a*, 4,23,24-trimethylcholest-22-en-3-one (XII), $R_1{=}R_2{=}CH_3$ or 4-methyl, 24-ethylcholest-22-en-3-one, $R_1{=}H$, $R_2{=}CH_2CH_3$; and *b*, 4,23,24-trimethylcholestan-3-one (VI), $R_1{=}R_2{=}CH_3$ or 4-methyl, 24-ethylcholestan-3-one, $R_1{=}H$, $R_2{=}CH_2CH_3$. The mass spectra of these pairs of compounds are identical. Hence, a definitive structure proof cannot be made at present.

It is well known that 4-methyl steroids are important biosynthetic intermediates in the formation of 4-desmethyl steroids[20], although they are present in only small amounts in plants. Hence, another possible source for sedimentary 4-desmethyl stanones is from oxidation of the 4-methyl stanones followed by decarboxylation (Fig. 1)[20].

The 4-methyl stanones could arise from oxidation of 4-methyl stenols to 4-methyl stenones followed by hydrogenation to the corresponding stanone (Fig. 1). In this regard relatively large amounts of 4-methyl and 4,4-dimethyl sterols are known to accumulate in the bacterium *Methylococcus capsulatus*[23]. An array of 4-methyl sterols with varying degrees of alkylation and unsaturation in the side chain have been found in several plants[18]. It is also important that 4α,23,24-trimethyl-5α-cholest-22-en-3β-ol (dinosterol) a stenol precursor to one of the structures of (XII), was found to be the major sterol in the toxic dinoflagellate, *Gonyaulax tamarensis*[9].

As mentioned earlier, no 4-methyl or 4-desmethyl stenones were detected. These compounds are proposed intermediates in our hypothesised transformation of stenols to stanols (Fig. 1).

Their absence may be due to a more rapid rate of hydrogenation relative to their rate of formation from stenol oxidation. Hence their steady-state concentration would be quite low. Work is now being carried out on other sediment samples from both oxic and anoxic environments to elucidate further the proposed transformations outlined above. We emphasise, however, that the proposed mechanism in Fig. 1 is probably only one of several degradation pathways for sterols in sediments.

Pathways leading to the formation of sterenes from stenols have been proposed by several authors[1,22,24–28]. These transformations in Recent marine surface sediments can be envisaged as a series of oxidation, reduction, and dehydration reactions. The sampling site off the south-west coast of Africa is an area of intense upwelling and high productivity. The presence of known microbiological products[20,29] such as stanols[30] (C. Lee, unpublished results), stanones and sterenes[1] in the sediments and the rapid rate of sediment deposition in this sampling area suggests microbially mediated transformations. For example, cholest-4-en-3-one and 5α-cholestan-3-one have been proposed as intermediates in the microbial reduction of cholesterol to cholestanol[29]. However, little is known about the metabolism of marine bacteria, and much more information is required to understand more fully the processes influencing the transformation reactions of steroids in marine sediments.

We thank J. Farrington, S. Henrichs, C. Lee and O. C. Zafiriou for helpful comments, C. Lee for unpublished data, and J. Farrington and C. Lee for help with the sediment sampling and analyses, also the Oceanography Section of the NSF for grants OCE 74-09991 and OCE 77-26084, and the Office of Naval Research, contact no. Geological evidence in favour of a Jotunheimen Caledonian suture

EARLY plate-tectonic reconstructions of the proto-Atlantic by Wilson[1] and Dewey[2] placed a Caledonian suture through central, southern Norway. Later, more detailed interpretations generally favoured a single (proto-Atlantic, Iapetus) suture off the west coast[3–14], in agreement with the pre-plate-tectonic orthodoxy[15–18] of a western, eugeosynclinal source for the far-travelled (up to 1,000 km) (ref. 13), crystalline and supracrustal nappes of Norway and Sweden. In South Norway, however, not all interpretations fitted this pattern. Goldschmidt[21] and Oftedahl[22] proposed a local root zone in the Jotunheim for the crystalline Jotun Nappe south-east of its present northwesterly margin. More recently Battey and McRitchie[23,24] demonstrated a close fit between surface geology and the interpretations of gravity data by Smithson *et al.*[25] of the Jotun Nappe as an 'Ivrea type' flake with a local root possibly as deep as 16 km. Note that recent[43] aeromagnetic results suggest a maximum thickness of only 5 km for the Jotun Nappe). Evidence from the northwestern margin of the Jotunheim is clearly critical, for the south-eastward transport of the Jotun Nappe deduced from areas to the south-east[14,18] is consistent with derivation from both the Iapetus suture and a possible Jotunheim suture. Some reports, however, apparently support the Jotunheim suture hypothesis. Between Fjaerlandsfjorden and Sogndalsdalen, Skjerli[26] found imbricated thrust slices of Basal gneisses and supracrustal rocks indicating transport to the north-west. A similar conclusion was reached by Battey and McRitchie[23] for Bøverdalen. Also, Elliott and Cowan[27] describe a sequence of tholeiitic greenstones with pillows and serpentinites from Holleindalen in Bøverdalen. Most recently, however, Roberts[42] has concluded, using structural evidence from seven traverses across the northwestern margin, that the Jotun Nappe was transported to the south-east. The work described here does not support this conclusion.

Within the Sygnefjell area (Fig. 1) an Assynt-type nappe culmination permits the examination of an extensive sequence of supracrustal rocks between the Basal gneisses and the overlying Jotun Nappe. Six main lithostructural units have been identified:

6	Jotun mangerites and anorthosites	Jotun Nappe; allochthon
5	Galdeberghytta gneisses	
4	Helgedalen metagreywackes	Parautochthon?
3	Turtagrø metavolcanics	
2	Sygnefjell sparagmites	
1	Basal gneisses	Autochthon

The Basal gneisses form part of the extensive northwestern Basal gneiss complex of South Norway. An early suite of

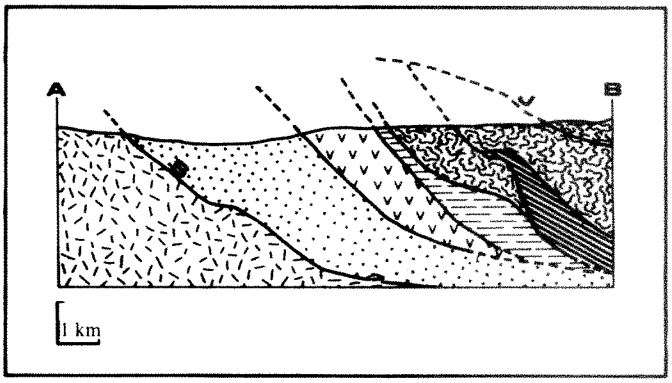

Fig. 1 A simplified lithostructural map of the Sygnefjell area: 1, Basal gneisses; 2, Sygnefjell sparagmites; 3, Turtagrø metavolcanics; 4, Helgedalen metagreywackes; 5, Galdeberghytta gneisses; 6, Jotun mangerites and anorthosites. St, Storevatnet; Sk, Skaalavatnet; Pr, Prestesteinsvatnet; H, Helgedalen; G, Galdeberghytta; K, Krossbu.

basic–intermediate rocks has been migmatised and metamorphosed in the almandine–amphibolite facies and intruded by foliated granites dated at 1,033 Myr (refs 28, 29).

Micaceous meta-arkoses (sparagmites) have, in places, a basal conglomerate resting unconformably on the Basal gneisses. They are intercalated with metalimestones, graphitic micaschists and hornblende schists higher in the sequence.

The Turtagrø metavolcanics comprise some 600 m of andesitic and basic lavas, some with pillows, and tuffs within a thrust bounded slice. This is overlain by up to 1 km of Helgedalen metagreywackes. The greywackes grade from a proximal, quartz-rich, conglomeratic facies at the base, to a distal, finegrained, apparently volcaniclastic facies towards the top. Graded bedding and various other sedimentary structures indicate deposition by turbidity currents, and provide evidence that the unit as a whole is the right way up.

All supracrustal units have been recrystallised in the greenschist facies. The absence of fossils or radiometric dates precludes a reliable assessment of their ages, although regional considerations[18,42] suggest an Eocambrian to Lower Ordovician age. Despite the thrusts within and between these supracrustal units, all are at present regarded as parautochthonous in view of the apparent lithological gradations between them. Moreover, all these units are intruded by pre-kinematic, minor gabbros, dolerites and diorites.

The Galdeberghytta gneisses at the base of the Jotun Nappe are partially mylonitised, amphibolitic and augen gneisses with K-feldspar-rich, late pegmatites and minor intrusives. The upper part of the Jotun Nappe consists of layered gabbros, leucogabbro, anorthosite and mangerites in various stages of retrogression from granulite facies, pyroxene-bearing assemblages. Battey and McRitchie[23] cite K–Ar age determinations of up to 1,280 Myr for these rocks to the south-east of the Syngefjell area.

Structural work has shown that both the Basal gneisses and the Jotun Nappe rocks were deformed and metamorphosed before the events that affected the supracrustal sequence. The supracrustal rocks share a common polyphase structural sequence. A transposed tectono-metamorphic banding was developed to varying degrees in all units during early deformations (D_1 and D_2). Where younging criteria can be identified, the D_1 folds face the north-west, suggesting relative transport in that direction. Intense flattening in the limbs of the D_2 isoclinal folds has resulted in discrete zones of mylonitic rocks. Following D_2, a phase of upright asymmetric folding (D_3) with the steep limbs overturned to the north-west took place syntectonically with major brittle thrusting (D_4) of all units (Fig. 2). The thrusting shows classical imbrication patterns, with the thrusts climbing section towards the north-west, indicating transport in that direction.

A similar structural geometry and history of folding has been described by Hopper (in preparation) from Østerøy near the northeastern margin of the Bergen Arcs, and by Cowan[31] from Bøverdalen. The Vassenden area, Bøverdalen, is one of those recently described by Roberts[42]. Both Cowan's (ref. 31 and personal communication) earlier work at Vassenden, and evidence from the nearby Sygnefjell area, indicate that a major phase of structures, including north-west facing folds (our D_1), pre-dated the D_1 of Roberts. Thus, in our view, the Vassenden area does not provide good evidence for nappe transport from the north-west.

An outline of the sequence of events in the Sygnefjell and nearby areas together with suggested broader interpretations can now be given.

First, pre-Sveconorwegian[23,29,32] high grade metamorphism and deformation of Jotun Nappe rocks (and of the north-west Basal gneisses and southern gneisses of other areas[29,34,38]).

Second, Sveconorwegian (1,033 Myr) intrusion of Hestbrepiggan granite into Basal gneisses.

Third, post-1,033 Myr (Eocambrian to Lower Palaeozoic?): (1) deposition of a fining-upwards sequence of conglomerates, limestone and shale; (2) sub-aqueous basaltic volcanism (ocean spreading); (3) andesites and turbiditic, volcaniclastic greywackes (island arc–trench system); (4) greenschist facies metamorphism and deformation of supracrustal wedge (ocean closure); (5) thrusting of the Jotun Nappe to the north-west (after flaking from lower crust during final stages of ocean closure); (6) broad warping and sinistral wrench faulting (after ocean closure).

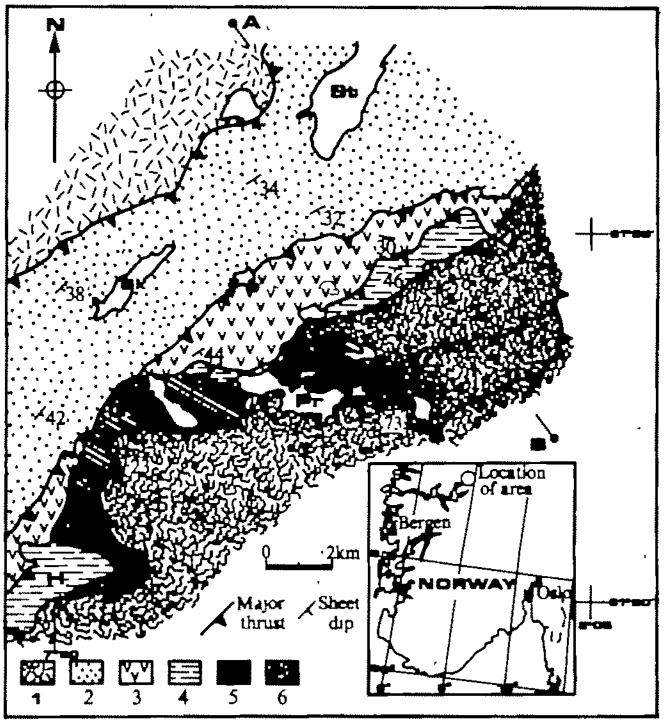

Fig. 2 A simplified dip section of the Sygnefjell area; the area has an along-strike relief of 1 3 km. J, Jotun Thrust; S, Sole Thrust; A–B, ornament as on Fig. 1.

Long distance southeastward transport of the Jotun Nappe has been suggested in the past for two main reasons. First, on the similarity of the Jotunheim and Bergen Arc high-grade metaplutonic rocks. Deep crustal granulite facies rocks are not uncommon in old basements, however, and many Jotun Nappe rocks can be matched in the basements both to the north-west and to the south-east of Jotunheimen (see refs 33, 39, 40). In any case, lithological similarity alone cannot indicate the direction of nappe transport.

Second, the occurrence in the nappe region of east to southeast trending penetrative lineations has been taken (see ref. 16) to indicate a southeastward direction of nappe transport. In the Sygnefjell area the early, penetrative lineation is due to the superimposition of at least two strains (D_1 and D_2) and a transport direction cannot be deduced from this evidence alone. Similar conclusions have recently been reached in the Bergen area by Faerseth *et al.*[41] and one of us (F.W.M.H., in preparation).

Within the Sygnefjell area, two groups of observations are consistent with the hypothesis of a Jotunheim suture:

First, the facing directions of the early folds (D_1), and, especially, the thrust geometries produced during the main movement phases (D_4), indicate tectonic transport to the north-west.

Second, the occurrence of a probably parautochthonous, oceanic, supracrustal sequence of arkoses, turbiditic greywackes, serpentinites and basaltic and andesitic volcanics.

On the other, southeastern margin of Jotunheim, it is well-established that both the supracrustal and the crystalline nappes were transported towards the south-east. That the supracrustal nappes moved considerable distances (100–270 km) is shown by Hossack's[14] recent unravelling of the thrust stack. The even greater distance of transport (290+km) 'assumed' (ref. 14 p 239) for the crystalline, Jotun Nappe above, although consistent with evidence from the supracrustal nappes, is not required by it, as Hossack clearly recognises. When the Sygnefjell evidence is also considered, a possible interpretation emerges of the Jotun Nappe as a flake detached from local, lower crust and thrust over (underthrust by) gneissose basements and marginal sedimentary basins both to the north-west (such as Sygnefjell) and to the south-east (such as Bygdin). The presence of igneous rocks within the northwestern supracrustals may indicate their proximity to the site of an active trench.

Further work will test the hypothesis of a Jotunheim Caledonian Suture. The structural evidence reported here will be published in full elsewhere.

Mechanism of reaction in metal + metal oxide systems

PYROTECHNICS frequently consist of intimate mixtures of powdered metals and metal oxides. The exothermicity of such reactions is often very high, as, for example, in the thermite process. Considerable self-heating occurs and the reaction often becomes explosive. Little experimental work has been carried out on the mechanism of these reactions, largely because the participation of solid phases and the high evolution of heat make them difficult to study. It is to be expected, however, that such mechanisms would normally involve solid phases, with the possible addition of a liquid phase when a low melting point reactant or intermediate is present. We report here that such reactions often occur through a gas phase process. Furthermore, when one of the constituents is magnesium, which is frequently the case in pyrotechnics, the reaction rate is controlled almost solely by the evolution of magnesium vapour.

The classical method, developed by Wagner[1] and by Tubandt[2–4], for elucidating the identity of the mobile species and of any intermediate compounds formed, is to allow pressed pellets of the two separate solids to react together. The movement of the phase boundaries and the growth of intermediate zones of different composition then provide the required information. During preliminary studies on metal + metal oxide systems, using this technique, it was discovered that reaction proceeds normally even when there is a substantial gap between the two solids, and the system is well below the melting point of the materials involved. This demonstrated that the mobile species was present in the gas phase and the chemical reaction involved both gaseous and solid components. A more comprehensive series of experiments was then carried out.

A typical reaction chamber consisted of a pair of mild steel 'crucibles', each of 8 mm internal diameter and 8 mm internal depth. The reactant samples were ground and sieved to the required particle size and quantities of about 0.2 g were packed into each crucible to the required pressure. The crucibles were heated separately *in vacuo* to remove occluded gases and were then handled only in dry, O_2-free conditions. After weighing, the crucibles were clamped together so that the reactant surfaces were about 2 mm apart and the complete reaction chamber was heated in a thermostatted oven, either *in vacuo* or in a low pressure of argon, for the required period (typically 1 h). At the end of the experiment, the two crucibles were separated and re-weighed to determine the mass of material transported (typically ~40 mg, corresponding to 2 mmol of reaction or 20% conversion). The product layers were then separated manually for analysis. Blank experiments were also carried out on the individual components.

The main results are shown in Table 1, from which the most

Table 1 Summary of metal + metal oxide reactions

System	$\Delta H^0_{f,300}$ of oxide (kcal mol^{-1})	$\Delta H^0_{f,300}$ per atom of oxygen	Temperature of reaction (°C)	Mobile species	Products identified
$Mg+SiO_2$	210	105	625	Mg	MgO, Si, Mg_2Si
$Mg+Cr_2O_3$	275	91	625	Mg	MgO, Cr, $MgCr_2O_4$

important conclusion is that, in the majority of cases involving magnesium, which has a vapour pressure of ~2 torr at these temperatures, the mechanism simply involves evaporation of magnesium from the solid followed by reaction at the oxide surface, in one or more stages. In such cases, the rate is determined primarily by the rate of evaporation of magnesium, an exception being the reaction with boric oxide.

When the oxide is less stable, as indicated by a lower heat of formation, the mobile species becomes oxygen. However, the mechanism involved is not simple dissociation of the oxide, for the following reasons. (1) In the absence of the metal reactant, the weight loss from the oxide was negligible (as would be predicted from the dissociation pressures). (2) In the presence of a non-volatile metal, the reaction was much slower and required a substantially higher temperature. (3) The extent of reaction was comparable with that of systems in which magnesium was transported. (4) Some of the magnesium oxide (~5%) was detected on the Ni/NiO surface.

It seems, therefore, that the dissociation of the oxide to give mobile oxygen is 'catalysed' by the presence of metal, presumably due either to the considerable heat evolved on reaction, thus raising the temperature of the oxide surface, or to the formation of intermediates of different composition.

Attempts to compare the kinetics of reaction using this technique were of only limited value for two reasons: first, the initial rate of evaporation of magnesium depended very much on its pretreatment and was thus rather irreproducible, and second, because the rate decreased markedly with time, due presumably to inhibition by solid product, the extent of reaction tended to be similar even when the initial rates differed. Quantitative kinetic studies will require a controlled and measurable pressure of magnesium vapour.

We thank the Procurement Executive of the Ministry of Defence for a grant in support of this work.

Photosynthesis in some British coastal waters may be inhibited by zinc pollution

RIVER drainage from mineral-bearing and industrialised regions has produced elevated concentrations of heavy metals in several parts of the coastal waters around the UK, including Liverpool Bay[1,2], Cardigan Bay[1], the Bristol Channel[1-3], off the mouth of the River Tees[4] and in the Firth of Clyde[5]. Little attention has been paid, however, to the possibility that the presence of the metals might be affecting the planktonic marine life of these sea areas. Phytoplankton represent the basic food resource on which the majority of marine animals and fish directly or indirectly depend, and it is thus conceivable that inhibition of their growth by toxic metals could have repercussions throughout the local marine food webs. We are investigating the role of trace quantities of both biologically beneficial and toxic substances in regulating the 'quality' of seawater, that is, its capacity to support and maintain, through photosynthesis, the production of living matter from the inorganic nutrients present in the water. As part of this research programme, we have examined how carbon fixation rates in natural populations of phytoplankton are affected by zinc concentrations encompassing those observed in the areas mentioned. Although zinc is a component of many enzyme systems[6] and therefore essential for the growth of phytoplankton[7], it becomes toxic if present greatly in excess of their basic requirements. We report here data which suggest that phytoplankton growth could be depressed by the zinc concentrations present in some British coastal waters.

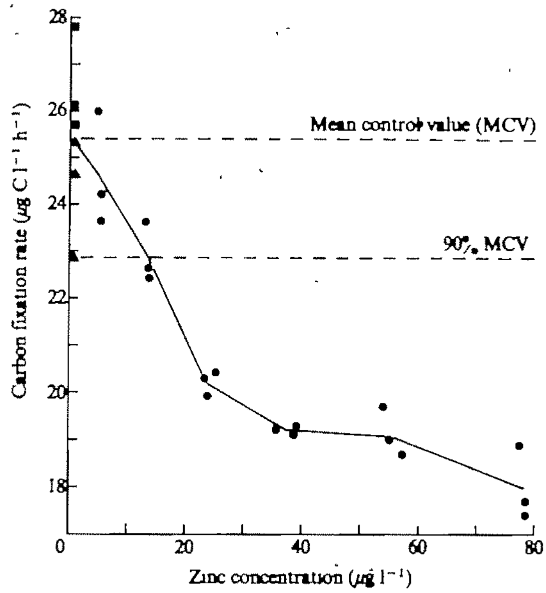

Fig. 1 The effect of increasing concentrations of zinc on the rates of carbon fixation in the phytoplankton present at Station L4 (50°15′ N, 4°13′ W) in the English Channel on 10 July 1978. The lines connect the mean values of each group of results. The measurements were carried out at 14 °C and 10 klx of illumination by Northlight fluorescent lighting. Sample 1 contained 2 1 µg chlorophyll *a* per l, the phytoplankton being almost exclusively diatoms of the genus *Rhizosolenia*. The chlorophyll *a* concentration has been corrected for the presence of phaeo-pigments ▲, ■, Controls.

Full details of the techniques being used will be published elsewhere. Briefly, samples of surface seawater, strained through a 170-µm nylon mesh to remove the zooplankton, were rapidly transported from the point of collection—Station L4 about 10 km south west of Plymouth breakwater—to our laboratory. During the journey, the samples were kept at seawater temperature and exposed to natural lighting conditions. Immediately after their arrival in mid-afternoon, zinc labelled with ^{65}Zn was added to eight 1-l subsamples of the water to give initial concentrations ranging from those present naturally (in the two controls) up to about 90 µg l^{-1}. The subsamples were then placed in an illuminated incubator maintained at the temperature of the seawater at the time of collection and left there overnight to allow the added zinc to equilibrate with the plant cells. The water was aerated throughout the whole of this period in the laboratory to maintain a constant pH and keep the phytoplankton in suspension. Between 20.00 and 06.00 h, the lights were extinguished to simulate overnight darkness. The next day, the carbon fixation rates of the phytoplankton in each of the subsamples were determined in triplicate in the illuminated incubator by measuring the rate of incorporation of $^{14}CO_2$ (ref. 8). Discrimination between the β and γ radioactivities due to the ^{14}C and ^{65}Zn, both in the water and in the phytoplankton (after their removal from the water by membrane filtration), allowed the carbon fixation rates and the amounts of zinc taken up by the plant cells (expressed as µg Zn

0028-0836/79/0277—0292$01.00

per µg chlorophyll *a*) to be determined as functions of the concentration of zinc present in the water during the carbon fixation measurement. The zinc concentration at this stage of the experiment was always lower than that initially, due to adsorption on to the glassware used to contain the water samples.

Figures 1 and 2 show the results of the measurements on one of the samples. Two further samples collected on successive weeks contained phytoplankton populations consisting of approximately equal numbers of dinoflagellates (mainly *Scrippsiella* aff. *trochoidea*) and diatoms (mainly *Rhizosolenia* spp.); carbon fixation rates in these were similarly depressed by the presence of zinc. In a control experiment, the normal routine was carried out with the exception that zinc was not added to any of the eight subsamples. In this case, the carbon fixation rates in each of the 24 final determinations agreed to within ± 10% of the mean value. In Fig. 1, fixation rates less than 90% of the mean control value can thus be regarded as due to perturbations caused by the zinc.

The results show that zinc concentrations down to 15 $\mu g\, l^{-1}$, and possibly lower, inhibited photosynthesis in the phytoplankton populations present in the English Channel in July 1978. The degree of inhibition was, however, a nonlinear function of the zinc concentration and above about 30 $\mu g\, l^{-1}$, there was very little further decrease in the carbon fixation rates. This was apparently due to the near saturation of the plant cells with zinc at the higher concentrations, as the zinc/chlorophyll *a* ratios in the phytoplankton were then approaching their maximal values (Fig. 2); the forms of these zinc sorption isotherms were found to differ from one sample to the next, probably due not only to the change in the species composition of the phytoplankton present in the water but also, to some extent, to uptake on to detrital matter which it was not possible to separate from the plant cells. These observations support the recently expressed view[9] that the effect of metals on the growth of phytoplankton is more closely related to the amounts accumulated by the plant cells than to the concentrations in the water surrounding them.

In the contaminated sea areas, dissolved zinc concentrations between 5 and 10 $\mu g\, l^{-1}$ were found to be widespread and at many locations, sometimes greatly, exceeded 10 $\mu g\, l^{-1}$ (refs 1–3, 5). Thus, it seems possible that primary production in these regions may already have been depressed as the result of metal pollution, particularly when it is remembered that zinc was just one of a range of metals usually present in the water[1–5], and synergistic effects as observed with zinc and copper mixtures in laboratory cultures[10] could amplify their individual toxicities towards the phytoplankton.

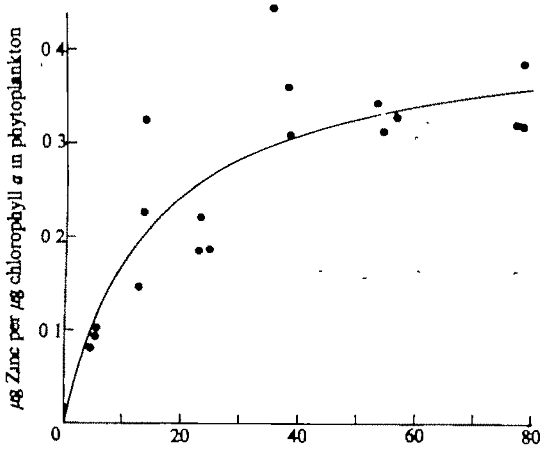

Fig. 2 Zinc/chlorophyll *a* ratios in the phytoplankton during measurement of the carbon fixation rates in relation to the zinc concentration in the seawater. The curve represents the best fit of the Langmuir adsorption isotherm $y = Ax/(B+x)$ to the data, the values of A (µg Zn per µg chlorophyll *a*) and B (μg Zn l^{-1}) used to compute it being 0.42 and 14.7

However, because our measurements were short term and relate to phytoplankton growing in the relatively unpolluted waters of the English Channel, extrapolation of the present data to other sea areas can only be made with some reservations. First, the metal contamination is generally associated with river drainage so that the polluted seawater is also likely to contain higher than usual levels of dissolved organic matter[11]. The formation of metal–organic complexes would decrease the biological availability of the metals and hence the amounts taken up by the phytoplankton, thereby moderating their effects in the way that chelating agents reduce the toxicity of copper in phytoplankton cultures[12]. Second, chronic exposure of metal-sensitive phytoplankton populations to sublethal metal concentrations might eventually lead to their replacement by tolerant species or the development of resistant strains[13] which would be unaffected by the presence of toxic metals. Nevertheless, the existence of potentially harmful zinc concentrations in our coastal waters clearly requires further investigations.

We thank D. S. Harbour for identification of the phytoplankton.

Widespread occurrence of a unicellular, marine, planktonic, cyanobacterium

IN marked contrast to their freshwater counterparts, marine planktonic cyanobacteria are restricted to a few nostocalean genera, of which only *Trichodesmium* is capable of forming extensive water blooms[1–3]. We report here the widespread occurrence of a small, marine, chroococcalean cyanobacterium belonging to the genus *Synechococcus*.

Natural water samples were filtered through 0.2 µm Nuclepore filters, counterstained with Irgalan black[4]. The filters were examined with a Zeiss Standard microscope equipped with Neofluar objectives and an epifluorescent illumination system containing a 100-W halogen lamp, a BP 450–500 excitation filter, a LP 528 barrier filter and a FT 510 chromatic beam splitter. Using this system, phycoerythrin-containing cyanobacteria fluoresce orange and can be distinguished from phytoplankters that fluoresce red.

Phycoerythrin-rich unicellular cyanobacteria were observed at seven stations in the Arabian Sea in January 1977, at three stations off the coast of Peru in March 1978, in Slope Water north of the Gulf Stream in April 1978, and periodically in Woods Hole Harbor. In the relatively rich waters of the Arabian Sea and off the coast of Peru, the population varied from 10^4 to 10^5 cells ml^{-1} within the euphotic zone (Table 1). The greatest number of cells was found within the top 20 m of the water column, with occasional cells being observed as deep as 400 m. In contrast, the surface sample collected from Slope Water north

0028-0836/79/0277—0293$01 00

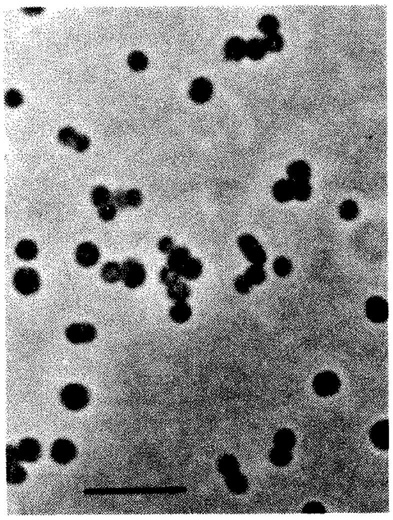

Fig. 1 Phase contrast photomicrograph of *Synechococcus* sp. (strain Syn-48) illustrating general cell morphology (scale bar, 5.0 μm).

of the Gulf Stream contained 1.3×10^3 cells ml^{-1}. In Woods Hole Harbor, counts have ranged from 2×10^3 cells ml^{-1} on 1 May 1978 to 3.6×10^5 cells ml^{-1} on 1 June 1978, at which time 15–20% were in a late stage of binary fission.

No attempt was made to culture the cyanobacteria from the above locations. However, in 1965, one of us (R.R.L.G.) isolated a small, red, coccoid cyanobacterium (strain Syn-48) off the north-east coast of South America (08°44′ N, 50°50′ W) with morphological and fluorescent properties similar to the cyanobacteria observed in open ocean waters by epifluorescence microscopy. Its size is $0.9–1.3 \times 1.8–2.2$ μm and it divides in one plane (Fig 1). Examination of thin sections by transmission electron microscopy reveals that it has a typical synechococcoid ultrastructure, with the thylakoids arranged peripherally. H. W. Siegelman (personal communication) reports that its pigment system is typical of other cyanobacteria, containing chlorophyll *a* as its major photosynthetic pigment and phycobiliproteins as accessory pigments. It always appears red in culture, due to both a predominance of phycoerythrin, one of the accessory photosynthetic pigments, and its inability to adapt chromatically[5,6]. The strain was isolated from a depth of 75 m where the salinity was 35.87‰. Preliminary growth experiments, carried out as described by Hargraves and Guillard[7], reveal that it will not grow at salinities below 14‰, indicating that it is intrinsically marine[8,9].

Recently, several additional strains of small, red, coccoid cyanobacteria have been cultured from Georges Bank and the Sargasso Sea. In general, they resemble both strain Syn-48 and the cells observed by epifluorescence microscopy. Individual isolates vary from 0.8 to 2.0 μm in diameter following binary fission.

Table 1 Representative vertical distributions of *Synechococcus* sp.*

* 10^4 Cells per ml.

Cell size and shape accompanied by division in one plane indicate that these cyanobacteria are assignable to the genus *Synechococcus*[10], an assignment which is further substantiated by the typical synechococcoid ultrastructure of strain Syn-48. The range in cell size among the isolates now in culture suggests that they may represent more than one species.

The use of epifluorescence microscopy to visualise the natural orange fluorescence of phycoerythrin seems a useful technique to enumerate small, phycoerythrin-containing unicellular cyanobacteria. However, not all cyanobacteria contain phycoerythrin, so that the specific set of filters used in this study cannot be used to count unicellular cyanobacteria in general. Furthermore, phycoerythrin is not unique to cyanobacteria but is present in almost all red algae (Rhodophyta) and in many cryptomonads (Cryptophyta). In principle, members of the latter two groups could interfere when attempting to count unicellular cyanobacteria, but in practice differences in size and chloroplast morphology should permit the unambiguous distinction between these eukaryotic algae and unicellular cyanobacteria.

Cyanobacteria have an ancient marine history[11] and show a considerable diversity and abundance in other marine habitats (for example, the intertidal zone)[1,2]. The existence of small unicellular cyanobacteria with a widespread geographical distribution and the ability to achieve considerable cell densities represents the second example of a planktonic cyanobacterium that has adapted to growth in the open ocean and the first well documented member of the Chroococcales to do so. The ecological importance of these cyanobacteria as major primary producers in the world's oceans is still to be assessed.

Pollen dispersal and optimal outcrossing in *Delphinium nelsoni*

NATURAL SELECTION, in sexually reproducing plants, should often favour matings between individuals of intermediate genetic similarity. Matings between very similar individuals may lead to inbreeding depression because segregational load is revealed[1,2], while matings between very dissimilar individuals may disrupt favourable gene combinations and lead to outbreeding depression[3-5]. Outbreeding depression in plants has

0028-0836/79/0277—0294$01.00

been documented in crosses between species, varieties and isolated populations[6–9], and reports of inbreeding depression date back at least a century[10]. We suggest that outbreeding depression will often occur on a much finer scale than previously recognised, especially in plants subject to restricted pollen and seed dispersal. Such plants are likely to show pronounced microgeographic genetic differentiation resulting from drift in subpopulations isolated by distance or from adaptation to local edaphic and biotic conditions[11,12]. Under these circumstances, a short outcrossing distance may be optimal not only because of intragenotypic effects, but also because it produces offspring sufficiently similar to the female parent to grow successfully near her, yet sufficiently genotypically diverse to maximise success of the total progeny in the face of coarse-grained temporal environmental variation[13–15], frequency-dependent sibling competition[16–18] or predation[19–20]. Here we present evidence that a short outcrossing distance is optimal for *Delphinium nelsoni* Greene and discuss the relationship between the optimal outcrossing distance for *D. nelsoni* and actual pollen dispersal by its main pollinators.

D. nelsoni is an herbaceous perennial which flowers in early summer around the Rocky Mountain Biological Laboratory (RMBL) in western Colorado[21]. It lacks clonal spread, the flowers are usually borne 10–20 cm from the ground and seeds drop an average of 11.2 cm from the central stalk. To investigate the effects of outcrossing distance on fitness, we hand-pollinated 1,016 flowers on 317 representative *D. nelsoni* plants near RMBL in 1976, 1977 and 1978. In the 1976 Meadow 1 and 1977 Meadow 2 experimental replicates, we bagged recipient plants to exclude natural pollinators and chose pollen donor flowers either from the same plant (self pollination) or from plants 1, 10, 100 or 1,000 m distant. In the 1977 Meadow 1 replicate we omitted 1 and 100 m treatments, while in the 1978 Meadow 1 replicate we substituted 3 and 30 m for selfed and 1,000 m treatments. Different pollen donor populations were used for Meadows 1 and 2, which are separated by 300 m of aspen forest and differ by 60 m elevation. We assigned each plant at random to a single distance treatment to avoid systematic bias in plant size or ovule number per flower, and used individual pollen loads from that distance to pollinate several of its flowers as they became receptive. Pollen loads were collected on circular toothpicks, usually from one donor flower but where dehiscing anthers were scarce from as many as three flowers on two plants. This collection technique was consistent between treatments within a replicate. In the 1977 Meadow 2 and 1978 Meadow 1 replicates, we equalised the amount of mechanical handling of pollen during transport from the donor population and the total elapsed time between its collection and deposition across treatments. We harvested fruits on recipient plants just before dehiscence and counted all fully developed seeds. Our hand pollination procedure consistently resulted in seed sets of approximately 15–35% of open-pollinated averages[21]. In all replicates, we left several flowers per plant unpollinated to serve as controls for failure of bags to exclude pollinators. We discarded the few plants in which these control flowers set copious seed, as *D. nelsoni* is protandrous and rarely sets seed when pollinators are effectively excluded[21]. In the 1976 Meadow 1 replicate, we lumped all mature seeds for each treatment and planted them in a 10 m^2 plot near Meadow 2. In the 1977 Meadow 1 replicate we lumped mature seeds from each plant and planted each progeny separately within a 2 m^2 plot in the center of Meadow 1. These plots were censused in early June during subsequent summers to determine seedling survivorship.

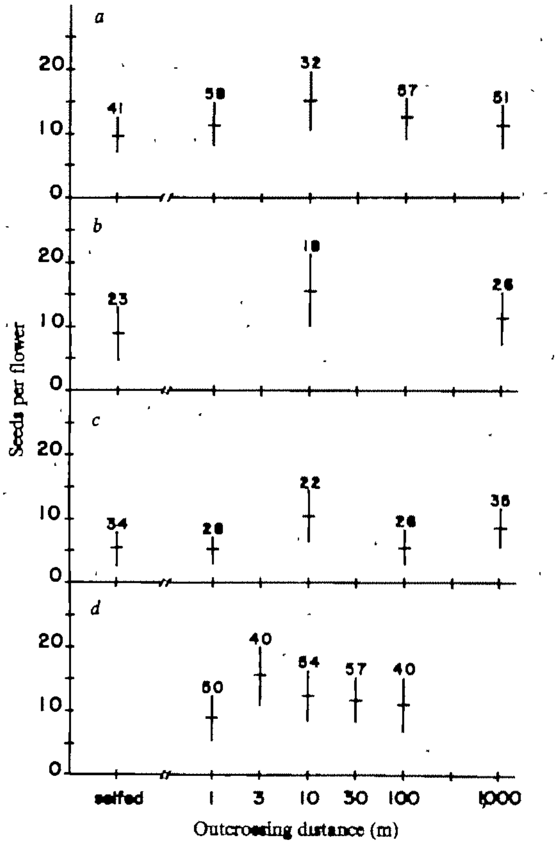

Fig. 1 Effects of outcrossing distance on seed set in hand-pollinated *D. nelsoni*. *a*, Meadow 1, 1976; *b*, Meadow 1, 1977; *c*, meadow 2, 1977; *d*, meadow 1, 1978. Values are means ±95% confidence units, with sample sizes shown. Two statistical tests establish significance of the intermediate outcrossing optimum. First, for the three 1976–77 experimental replicates, 10 m seed sets were significantly higher overall than either 1,000 m (d.f. = 6, $\chi^2 = 12.59$, $P < 0.05$) or selfed (d.f. = 6, $\chi^2 = 24.20$, $P < 0.005$) seed sets, using combined probabilities from separate one-tailed *t* tests with each replicate[22]. Second, the probability of observing by chance alone an intermediate optimal outcrossing distance in the 1976 replicate, followed by peaks at the same distance interval for the remaining three replicates is $3/5 \times 1/3 \times 1/5 \times 3/5 = 0.024$

Table 1 Effects of outcrossing distance on seedling survivorship in *D. nelsoni*

	Treatment				
	Selfed	1 m	10 m	100 m	1,000 m
1977 Meadow 1 seeds, planted in Meadow 1, censused after 1 yr					
No. planted	58	—	145	—	116
No. surviving	3	—	23	—	13
Proportion surviving	0.052	—	0 159	—	0.112
1976 meadow 1 seeds, planted in Meadow 2, censused after 2 yr					
No. planted	98	98	98	98	98
No surviving	0	3	7	1	1
Proportion surviving	0	0.031	0.071	0 010	0 010

A significantly higher proportion of 10 m seeds survived overall than either 1,000 m (d f. = 4, $\chi^2 = 13.47$, $P < 0.01$) or selfed (d.f = 4, $\chi^2 = 28\ 30$, $P < 0\ 005$) seeds, using combined probabilities from separate one-tailed *t* tests of differences of proportions with each replicate[22].

For all hand pollination experiments mean seed sets per flower were highest with an intermediate outcrossing distance and declined significantly at longer and shorter distances (Fig. 1). The three 1976–77 replicates consistently indicate an optimal outcrossing distance of 1–100 m, whereas the 1978 replicate more precisely indicates an optimal distance between 1 and 10 m. Note that in Meadow 1 mean seed sets for each treatment were especially similar between years. An optimal outcrossing distance between 1 and 100 m again appeared in seedling survivorship in natural meadows, and inbreeding and outbreeding depressions in survivorship were also significant (Table 1).

The main pollinators of *D. nelsoni* in the RMBL area are broad-tailed hummingbirds (*Selasphorus platycercus*), occasional rufous hummingbirds (*S. rufus*) and bumblebees (primarily *Bombus appositus* and *B. flavifrons* queens)[21]. Pollen dispersal by these visitors was estimated in two ways in 1976: (1) Foraging pollinators were followed in Meadows 1 and 2, with observations of bees and birds matched by meadow, day, and

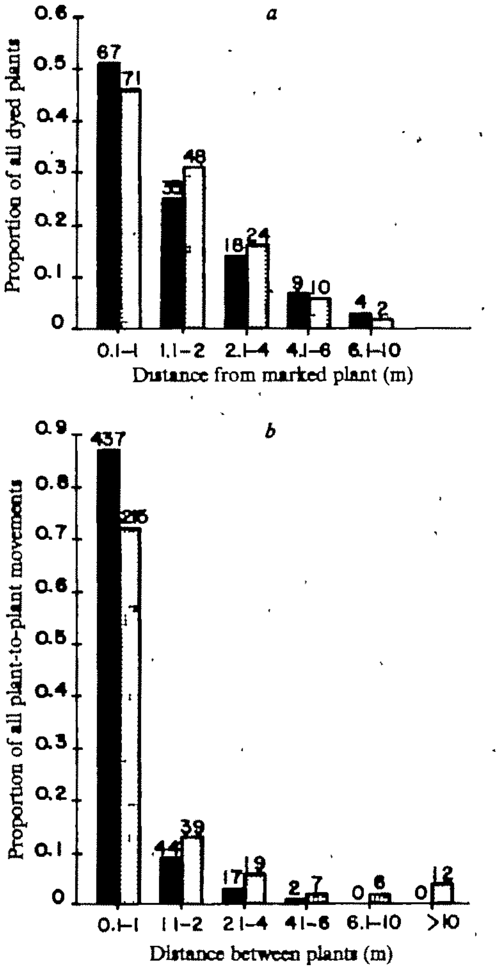

Fig. 2 Estimates of pollen dispersal by pollinators of *D. nelsoni*. *a*, Distributions of dye dispersal distances for caged (■)($\bar{x}$ = 1.64 m) and uncaged (□)($\bar{x}$ = 1.57 m) plants, with sample sizes (numbers of neighbouring plants receiving dye) shown *b*, Distributions of plant-to-plant movement distances for hummingbirds (□)(from 19 foraging bouts $\bar{x}$ = 2.1 m) and bumblebees (■)(from 12 foraging bouts $\bar{x}$ = 0.63 m), with sample sizes (number of movements) shown above each histogram.

time of day, and numbers of flowers visited per plant and distances flown between successive plants were noted. Densities in these meadows averaged 16 plants per m^2. (2) Dispersal of fluorescent pigments dusted on 18 plants in Meadow 2 was measured. Half of these plants were caged with chicken wire to exclude birds but not bees, and half were exposed to both pollinators. Caged and uncaged plants were dusted in pairs with distinct colours over a period of 2 weeks. Three to five days after dusting, neighbouring plants within a 10 m radius were sampled and scored for presence of pigment grains on floral parts contacted by pollinators.

Figure 2 compares distributions of plant-to-plant movements of hummingbirds and bumblebees and patterns of pigment dispersal from caged and uncaged plants. On average, birds moved 3.4 times as far as bees, but pigment moved no further from uncaged plants (exposed to birds as well as bees) than from caged plants. Movement distributions for bees and birds differ significantly overall ($\chi^2 = 21.0$, d.f. = 5, $P > 0.005$), while those for pigment from caged and uncaged plants do not ($\chi^2 = 2.5$, d.f. = 4, $P > 0.5$). Movement distributions for both pollinators are more highly leptokurtic than those for pigment, perhaps as a result of pigment carryover past the first recipient flower.

Expressing pollinator foraging only in terms of plant-to-plant movements conceals the fact that hummingbirds visit more flowers per plant than do bumblebees (birds, 2.5 ± 0.09 flowers per plant (296); bees, 1.4 ± 0.06 flowers per plant (502); values are means ± one s.e.m. followed by sample sizes). Counting within-plant movements as 0 m, mean flower-to-flower distances flown by the two pollinator types are more similar than mean plant-to-plant distances (birds, 0.8 ± 0.13 m between flowers (741); bees, 0.4 ± 0.03 m between flowers (731). Within-plant movements of hummingbirds are also especially likely to lead to selfing: birds appear to move unsystematically between flowers on an inflorescence, whereas our observations suggest that bees usually visit lower, pistillate flowers before moving up an inflorescence to staminate flowers[23,24].

The mean pollen dispersal distance estimated by these methods is about 1 m, the lower end of the 1–10 m range we construe from hand pollination to contain the optimal outcrossing distance for *D. nelsoni*. This discrepancy may indicate our inability to measure pollen flow directly or to define optimal outcrossing precisely using hand pollination. On the other hand, we do not necessarily expect to find congruence between actual pollen flow and that which is optimal from the point of view of female function. Instead, actual pollen flow can be expected to reflect: (1) conflicting selection on plants to maximise amounts of pollen received as well as to optimise transfer distances (for example, bees and birds may move more pollen than birds alone even though birds move slightly longer distances); (2) conflicting selection on plants to donate as well as receive pollen over optimal distances (for example, optimal dispersal distances may differ for male and female functions); or (3) conflicting selection on pollinators to minimise flight distances and on plants to achieve optimal outcrossing. In (3) it is difficult to see how plants can exert any major influence on pollinator flight distances by altering floral rewards. For this reason, the ability of plants to discriminate pollen genotypes after pollination[25–27] may be of major importance if they are to achieve optimal outbreeding, assuming that pollinators transfer some minimal amout of pollen an optimal distance.

Although we suggested that an intermediate optimal outcrossing distance could be caused by intragenotypic, intergenotypic, or genotype × environmental effects, our data most strongly implicate the first effect. Between-treatment differences in seedling survivorship appeared even though we planted seeds from 1976 hand pollinations in low densities far from the maternal meadow. As they occurred in the probable absence of sibling competition and in environments not similar to those of female parents, these differences suggest that physiological compatibility between parental genotypes is important in determining offspring fitness. We are now attempting to determine the importance of intergenotypic and genotype × environmental effects in molding the breeding system of *D. nelsoni*, by measuring the influence of seed dispersal distance, sibling competition, and environmental variation on the viabilities of variously outcrossed progenies.

Bimodal distributions of seedling weight in relation to density of *Festuca paradoxa* Desv.

THE degree to which plants growing together interfere with one another by competing for resources such as light, moisture and nutrients is difficult to determine by direct measurement of resource depletion[1]. Plant ecologists have therefore looked for indicators of interference in population structure[2,3]. One proposed measure of interference is the shift that occurs from the 'normal' distribution of seed weight to a 'log-normal' distribution of the weight of seedlings grown from those seeds in an even-aged monoculture. This shift presumably reflects the emergence of a few large and dominant individuals and the suppression of larger numbers of small individuals. Recently Ford[4] and Newbould[5] have proposed that distributions of plant weight in competing populations are actually bimodal, resulting from the presence of distinct populations of large individuals with positive relative growth rates and small individuals with nearly zero growth rates. Even-aged plantations of *Picea sitchensis* demonstrate such disjunct growth rates, and mortality is confined to the smaller individuals[4]. Size distributions in naturally thinning populations of *Abies balsamea* and *Prunus pensylvanica* are also bimodal[6]. We have studied the distribution of seedling weight in even-aged stands of *Festuca paradoxa*, a native North American prairie grass[7], and report here that although the distribution is bimodal, the bimodality is more striking at lower densities, where interference is less severe. This result is the reverse of that expected if the extent of bimodality were a direct indication of the magnitude of interference. Therefore, although bimodality may be an eventual outcome of interference, it cannot be used as a measure of the strength of interaction between individuals.

At the highest density (16 seeds cm^{-2}), distributions of ln-transformed seedling weight (Fig. 1) are only slightly or not at all bimodal. The distributions become increasingly bimodal as density increases. At the lowest density (1 seed cm^{-2}), the distribution appears most strongly bimodal. All distributions are significantly different from the normal distribution at the 5% level (*G*-tests[8]). Only the distributions at 16 seeds cm^{-2} show significant skewness (to the right[9]), but all are significantly platykurtic (flat-topped[9]). Platykurtosis is not sufficient to demonstrate bimodality, but bimodal distributions are platykurtic. There is no direct statistical measure of bimodality.

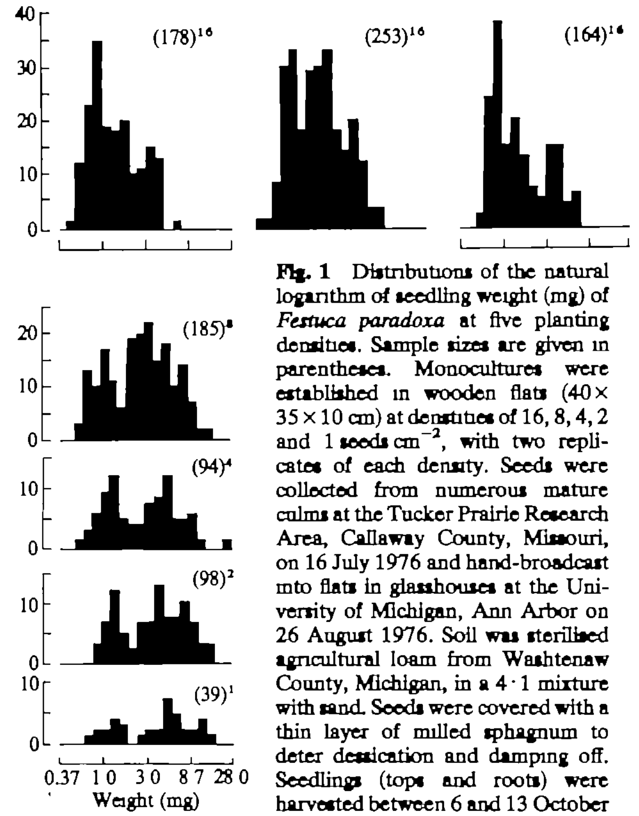

Fig. 1 Distributions of the natural logarithm of seedling weight (mg) of *Festuca paradoxa* at five planting densities. Sample sizes are given in parentheses. Monocultures were established in wooden flats (40 × 35 × 10 cm) at densities of 16, 8, 4, 2 and 1 seeds cm^{-2}, with two replicates of each density. Seeds were collected from numerous mature culms at the Tucker Prairie Research Area, Callaway County, Missouri, on 16 July 1976 and hand-broadcast into flats in glasshouses at the University of Michigan, Ann Arbor on 26 August 1976. Soil was sterilised agricultural loam from Washtenaw County, Michigan, in a 4 · 1 mixture with sand. Seeds were covered with a thin layer of milled sphagnum to deter desiccation and damping off. Seedlings (tops and roots) were harvested between 6 and 13 October 1976 in randomly-placed 5 × 5 cm plots, 3 for each density, washed to remove soil from the roots, dried at 80 °C for 24 h, and weighed on a Cahn electrobalance. For 8, 4, 2 and 1 seeds cm^{-2}, one-way anovas[8] showed no differences in seedling weight among the three replicates at the 10% level. Consequently, the replicates were lumped, and one distribution is shown. At 16 seeds cm^{-2}, the replicates differed at the 1% level ($F_s = 4.87$) and are shown separately. Distributions at 8, 4, 2 and 1 seeds cm^{-2} are all significantly different from the distributions at 16 seeds cm^{-2} (χ^2 tests[8])

The bimodality in the weight distributions is not due to an underlying bimodality of seed weight, either for the intact diaspore or for the caryopsis without accessory tissues (Fig. 2). Neither distribution deviates significantly from the normal distribution (*G*-tests[8]), and neither is skewed or kurtotic. The bimodality is not due to an underlying bimodality in germination time (Fig. 3). This distribution is significantly right-skewed and leptokurtic.

Mean seedling weight increases with decreasing density (Table 1), indicating that resource limitation is occurring at higher densities. The bimodal pattern emerges before density-dependent mortality. The ratio of seedlings harvested to seeds planted is not significantly different for the different densities (one-way anova with arcsine transform[8]). Mortality, if occurring, is uniform among the densities.

Interference is *a priori* more severe at higher densities. Our finding that bimodality is weaker at higher density suggests that at high density, the manifestations of interference in population structure are delayed and that the interaction between individuals is slowed. At the highest density, all individuals may

Table 1 Seedling weight of *Festuca paradoxa* at five planting densities

Planting density (seeds cm^{-2})	Sample size	Geometric mean of seedling weight ± s d. (mg)	Skewness g_1	Kurtosis g_2
16	178	1.40 ± 2.23	0.444*	−0.881*
16	164	1.58 ± 1.95	0.620*	−0.893*
16	253	1.73 ± 1.88	0.258†	−0.745*
8	189	2.78 ± 2.73	−0.086	−0.935*

0028-0836/79/0277—0297$01 00

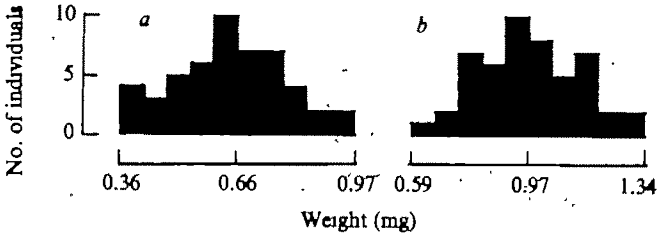

Fig. 2 Distributions of weights of excised caryopses (*a*) and intact diaspores (caryopses with lemmas and paleas) (*b*), obtained on a Cahn electrobalance. Arithmetic scale, sample size is 50 in both cases. For the intact diaspores, $\bar{x} = 0.967$ mg, $s = 0.170$, $g_1 = 0.129$ (not significantly different from zero[9]), and $g_2 = -0.576$ (NS). For the excised caryopses, $\bar{x} = 0.639$ mg, $s = 0.143$, $g_1 = 0.008$ (NS), and $g_2 = -0.502$ (NS). Neither distribution is significantly different from the normal distribution (*G*-test[8]).

suffer from more severe resource limitation; this idea is supported by the right skew in the data at 16 seeds cm^{-2}. The appearance of dominant individuals may be postponed. At lower densities, because resource limitation is less severe, growth is more rapid, individuals are larger, and the emergence of dominant individuals (and hence the bimodality) is more rapid.

Factors determining which individuals become dominant and which are suppressed remain somewhat obscure. Suppression is probably not due to genetic differences[10]. Seed size[11], order of emergence[12] and neighbourhood effects[13] have been implicated in determining which individuals become dominant.

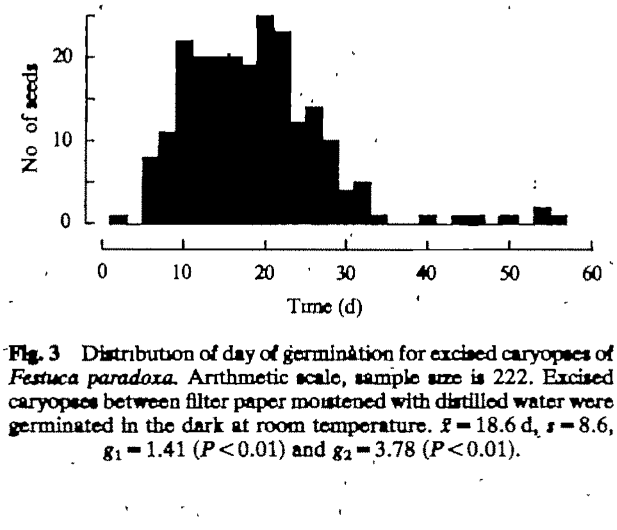

Fig. 3 Distribution of day of germination for excised caryopses of *Festuca paradoxa*. Arithmetic scale, sample size is 222. Excised caryopses between filter paper moistened with distilled water were germinated in the dark at room temperature. $\bar{x} = 18.6$ d, $s = 8.6$, $g_1 = 1.41$ ($P < 0.01$) and $g_2 = 3.78$ ($P < 0.01$).

While intrinsic factors generating bimodality cannot be exhaustively eliminated, the two most likely intrinsic sources (bimodality in seed weight or germination time) have been excluded here. The bimodality is probably a direct result of interference, although the possibility remains that severe interference prevents the expression of an intrinsic bimodality (due to other factors) at high density.

Disjunct populations with zero and positive growth rates are sufficient to generate a bimodality in distributions of ln-transformed individual weight. Bimodality appears to be an eventual structural result of interference and thus is a valuable descriptor of populational attributes. These results demonstrate the need to distinguish between populational attributes which characterise the pace and severity of interference from attributes which describe the outcome of interference.

A method for culture of micromanipulated sheep embryos and its use to produce monozygotic twins

MICROSURGICAL techniques have proved valuable for investigations of the regulatory capacity of early mammalian embryos, including the developmental potential of single blastomeres from two-, four- and eight-celled embryos (see ref. 1 for review). However, the usefulness of radical microsurgery in experiments on early cleavage stages has been restricted largely to species in which such young embryos may be cultured *in vitro*, notably the mouse, as, in most instances, embryos less advanced than the late morula stage fail to survive *in vivo* if the zona pellucida has been removed or substantially damaged[2–6]. There has been no satisfactory method for culture *in vitro* of early cleavage stages in the sheep; and consequently there have been few reports of attempts to micromanipulate early sheep embryos[7–9]. I describe here a method whereby micromanipulated eggs can be protected during their early development *in vivo* and its use in an investigation of the developmental potential of single blastomeres from two-celled sheep embryos with the aim of producing monozygotic twins. The method involves coating the eggs with agar after microsurgery so as to seal defects produced in the zona pellucida.

In preliminary experiments it was established that young sheep embryos embedded in agar and transferred to rabbit oviducts[10] continued to develop at a normal rate, even when the zona pellucida was extensively damaged, provided that they remained embedded in agar during the culture period. On the basis of this observation, a technique was devised which enabled the production of monozygotic twins.

Two-celled embryos were collected from super-ovulated donor ewes early on day 2 of their oestrous cycle (onset of oestrus: day 0). Embryos were collected, stored, micromanipulated and transferred in an enriched phosphate-buffered saline medium (PBS)[11]. During storage and manipulation the embryos were held at room temperature.

Monozygotic pairs of agar-coated single blastomere eggs were produced as follows. (1) The two-celled egg was held by suction with a capillary pipette, and the zona pellucida was ripped open along the interblastomeric groove for about three-quarters of its circumference with a fine glass needle. (2) The blastomeres were sucked out of the zona with the aid of a Pasteur pipette with a tip diameter sufficiently small to detain the zona while allowing the

0028-0836/79/0277—0298$01.00

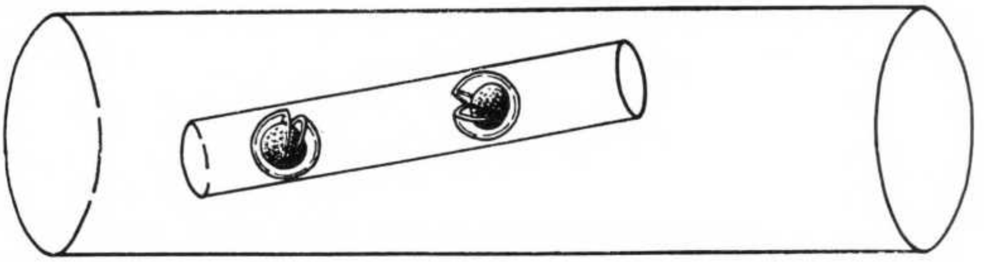

Fig. 1 Diagram of a pair of micromanipulated single blastomere eggs and agar embedding.

blastomeres to pass through. (3) The blastomeres were separated by gentle suction with a Pasteur pipette of smaller tip bore, allowing the passage of only one, slightly compressed, blastomere at a time. (4) Single blastomeres were injected with a capillary pipette into zonae evacuated as described above and held by suction. (5) A 1.2% solution of agar (Difco) in 0.9% NaCl in distilled water was prepared. While the solution was left to cool, the eggs to be embedded were transferred from PBS to sheep serum. (6) When the agar had cooled to 38–36 °C a few ml were poured into a Petri dish, and a monozygotic pair of single blastomere eggs was immediately transferred to the agar solution with a fine-bore Pasteur pipette to be picked up a few seconds later in a small amount of agar solution. The agar containing the eggs was held in the tip of the pipette for about half a minute and then expelled as a solid cylinder into PBS. The ends were cut off the cylinder so that the eggs were contained in a segment measuring 0.15×0.5–1.0 mm. (7) This tiny cylinder was in turn embedded by a similar procedure into a larger one, measuring 0.7×2.0–2.5 mm (Fig. 1). Procedures (1) and (4) were carried out with the aid of a Leitz micromanipulator and De Fonbrune suction/injection devices.

One to four agar cylinders, each containing a pair of monozygotic eggs, were transferred to each oviduct of ewes on days 1 or 2 of their oestrous cycle. To facilitate collection of eggs, the oviducts of recipient ewes were ligated at the utero-tubal junction. After $3\frac{1}{2}$ to $4\frac{1}{2}$ d the eggs were flushed from the oviducts and examined. Those embryos which had reached the late morula–early blastocyst stage were considered to have developed at a normal rate. Among the rest a distinction could be made between those which had undergone some development but were retarded and those which were completely degenerate (Fig. 2).

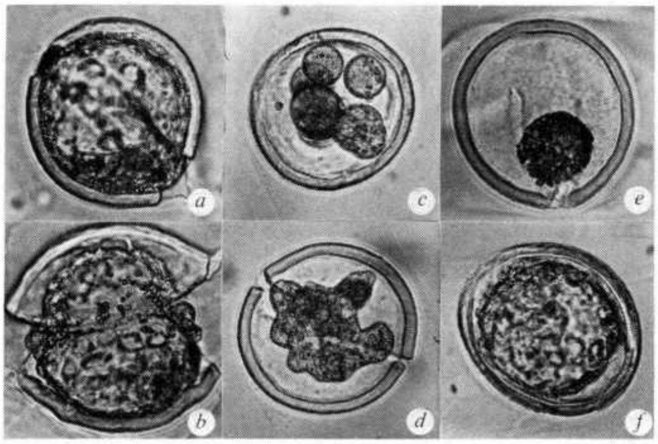

Fig. 2 Eggs from single blastomeres of two-celled sheep embryos after culture in sheep oviducts but still embedded in agar ($\sim\times400$). *a*, *b*, Monozygotic pair after $4\frac{1}{4}$ days' culture. Both eggs have developed at a normal rate and are early blastocysts. *c*, *d*, Monozygotic pair after $3\frac{1}{2}$ days' culture. *c* Is retarded in its development, whereas *d* has developed at a normal rate and undergone compaction. After fixation and staining, *c* was found to contain 8 cells, *d* 16 cells, all with morphologically normal nuclei. Normally, compaction is only evident in sheep embryos containing 30 or more cells. *e*, *f*, Monozygotic pair after $4\frac{1}{4}$ days' culture. *e* Is completely degenerate, whereas *f* is an early blastocyst. The large defects in the zonae pellucidae are visible in *a*, *b* and *d*. The main reason for inserting the single blastomeres into evacuated zonae was that the presence of the zona made it easier to remove the agar after culture, without damaging the embryo.

The results of this part of the experiment are summarised in Table 1. It is evident that very considerable losses of embryos resulted from inefficient micro- and macrosurgery on two-celled embryos and recipient ewes, respectively, but few embryos were lost in the course of the embedding procedure. Furthermore, all embryos recovered from the recipients had intact agar coatings, which made it a simple matter to recognise not only the original pairs, but also individual embryos within these pairs. The overwhelming majority of embryos recovered had also developed at an apparently normal rate. As observed in investigations of single blastomere mouse eggs[1,16], the time at which compaction and blastulation occurred reflected the age of the embryo rather than the number of cells it contained.

Table 1 Results of manipulation experiment

Pairs of monozygotic blastomeres	
Start of experiment (~no. of two-celled embryos)	61
After removal of zona pellucida, blastomere separation and injection into evacuated zonae	33
After embedding in agar	31
Transferred to ewes	31
Recovered from ewes	20
Stage of development of recovered single blastomere eggs	
Late morula or early blastocyst	35
Retarded	1
Degenerate	4
Monozygotic pairs in which both embryos had developed at a normal rate	16

Thirty-two late morulae and early blastocysts, constituting 16 sets of monozygotic embryos, were manipulated out of the agar with a pair of 24-g hypodermic needles, and transferred to ewes on days 5, 6 or 7 of their oestrous cycle. Each ewe received one pair of monozygotic embryos. Of 16 recipients, 11 became pregnant. One aborted a single fetus on day 100. The remaining 10 went to term, producing, in all, five sets of twins (Fig. 3) and five single lambs. This result represents an embryonic survival rate 10–15% below that expected following transfer of ordinary embryos on days 5–7 in sheep[12,13]. It is likely that damage resulting from the manipulations necessary to remove the agar before transplantation was responsible for the lower viability of embryos in the present experiments, and when the twinning rate is taken into consideration, it seems reasonable to conclude that each blastomere of a normal two-celled sheep embryo has the potential to develop into an entire lamb. In view of the work of Nicholas and Hall[14], Seidel[15] and Tarkowski[16] on single blastomeres of two-celled embryos of rat, rabbit and mouse, this result was not surprising, although the experiments of Mullen, Whitten and Carter[17], in which only one pair of monozygotic twins was obtained from the separated blastomeres of an unspecified number of two-cell embryos, suggested low viability of such 'half embryos'.

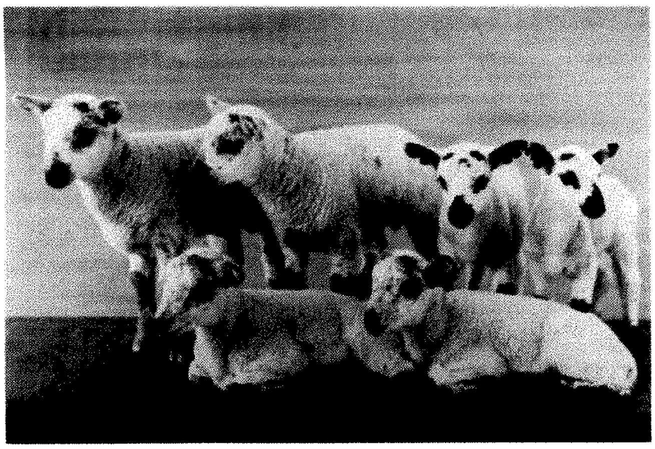

Fig. 3 Three sets of monozygotic twins produced by separation of the blastomeres of two-celled sheep embryos. Welsh Mountain cross-bred ewes, inseminated with Suffolk ram semen, were used as embryo donors. Note the general similarity in the distribution of pigmented areas, but also some minor differences between co-twins.

It may be predicted that the agar embedding method will prove useful, not only for culture *in vivo* of micromanipulated sheep eggs whether they be of the 'single blastomere' or the 'allophenic'[18] variety, but also in opening the way for similar experiments in other species, such as the pig and the cow, in which early embryos cannot yet be cultured *in vitro* with any high degree of success.

Chromosome polymorphism and sex determination in a wild population of tsetse

SEX in the Diptera is determined by a variety of genetic mechanisms ranging from the simple condition of male or female heterogamety to complex polygenic systems[1]. Studies of tsetse flies have shown the males of all species examined to be heterogametic XY with a heteropycnotic Y chromosome[2,3]. Such cytological heterogamety is found in many dipteran species but the presence of 'sex' chromosomes does not necessarily mean that they are involved in sex determination[4]. Although there have been no studies specifically related to sex determination in *Glossina*, it has been postulated that the system is similar to that found in *Drosophila*[5]. I report here on a natural population of *Glossina palpalis palpalis* (R-D) found to contain a high incidence of aneuploids, the composition of which may be used to explain the mechanism of sex determination in the genus.

Flies were caught at five sites on tributaries of the rivers Niger and Kaduna. The sites, Akerre, Kuje, Bwari, Guni and Gimi, are located within a 100-km radius of Minna in Niger State, Nigeria. Captured females were transferred to the laboratory where they were caged individually, maintained at about 25 °C and 60–70% relative humidity and fed on rabbits. Puparia produced were collected daily and when 5 d old were used for cytogenetic analysis. Brains were dissected from the pupae, cultured for 3 h in Eagle's minimal medium containing $1\ \mu g\ ml^{-1}$ colchicine and fixed in methanol–acetic acid. Air-dried chromosome preparations[6] were made from the brain tissue and stained routinely in toluidine blue.

Production of puparia by the wild-caught flies was poor, many females producing only one puparium, the maximum obtained from a single female being five. A total of 553 puparia was obtained from 249 females, an average of 2.2 puparia per female. The normal chromosome complement of *G. p. palpalis*[3] is $2n = 4+XY$, but 26 of the females in this study (10.4%) produced offspring which were aneuploid. Of these 35 abnormal pupae, 22, which were shown to be female by dissection, were found to have XXY chromosome complements, and one was found to be XXYY; seven pupae, shown to be male by dissection, were found to be XYY (Fig. 1), and a further five pupae were X0 males. All the females producing aneuploid pupae were also shown to be capable of producing normal XX female and XY male offspring. In the case of the five X0 pupae, each came from females which produced only one such aneuploid type, the

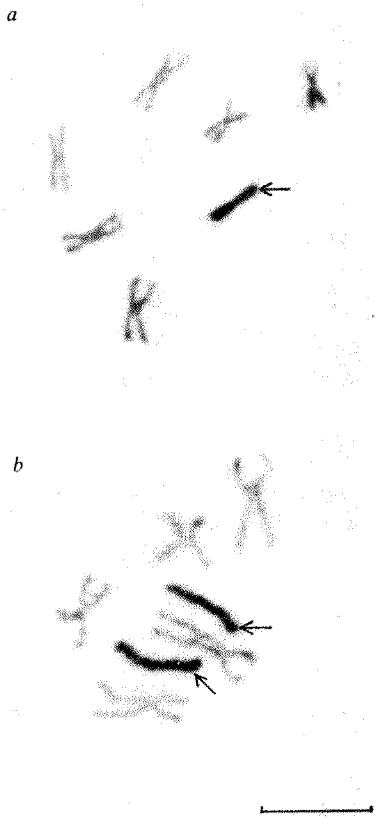

Fig. 1 Metaphase neuroblasts from 5-d-old embryos of *G. p. palpalis* showing sex chromosome aneuploidy. Arrows indicate Y chromosomes. *a*, Female, $2n = 4+XXY$; *b*, male, $2n = 4+XYY$. Bar = 10 μm.

0028–0836/79/0277—0300$01.00

rest of their offspring (average three puparia per female) being normal. These figures represent the pooled data from the five collecting sites, as no significant differences were found in the incidence of aneuploidy between sites.

The presence of an extra Y chromosome, or even two Y chromosomes, in female *G. p. palpalis*, and the absence of a Y in males were found to have no obvious phenotypic effect; thus, it may be concluded that sex in this species is determined by the number of X chromosomes present. This system of sex determination is clearly analogous to that demonstrated in *Drosophila* by Bridges' classical experiments with mutant strains[4]. It was later established that sex in *Drosophila* is determined by a system of genic balance between sex determinants on the autosomes and the X chromosome[7]. Such systems are common in insects[1] and it seems probable that the autosomes play a part in sex determination in *Glossina*; however, until useful genetic markers are available, this cannot be confirmed. The X0 male pupae found in the present study all had apparently normally developing testes, but the course of spermatogenesis could not be followed in pupae of this age. Such X0 males are completely sterile in *Drosophila* due to failures at spermiogenesis[8], but until greater numbers of X0 males are obtained, the precise role of the Y chromosome in *Glossina* remains uncertain, although it has been suggested that it may not be involved in sperm development[9].

The production of sex chromosome aneuploids in this population of *G. p. palpalis* can be accounted for by non-disjunction of the X chromosome during female meiosis, giving XX and 0 eggs, the fertilisation of which by normal sperm would give rise to the XXY females and X0 males found; XXY females when crossed with normal males can be expected to produce XYY males[4]. However, the frequency of spontaneous primary non-disjunction in female *D. melanogaster* is known to be very low (0.05–0.1%)[10], and, although such data are not available for *Glossina*, the occurrence of 21 females (8.4%) in the present sample shown to be XXY (by producing XXY, XYY, XX and XY pupae) suggests that they are being maintained in the population as a polymorphism rather than by spontaneous non-disjunction. As *G. p. palpalis* is an important vector of sleeping sickness in West Africa, it may be of practical value to determine what selection pressures, if any, are maintaining this polymorphism in the population, as the epidemiology of the disease is intimately associated with the ecology of the fly[11].

If, as suggested here, sex determination in *Glossina* is controlled by a polygenic system, then it is probable that sex ratio-distorting factors are present in the tsetse genome. Such factors are commonly found in other Diptera, including mosquitoes[12] and house flies[13], which are known to have complex sex-determining mechanisms; indeed, it has been suggested that segregation distortion may be a means whereby mutant sex determinants become established in a population[14]. Sex-ratio distortion has been induced in *G. morsitans* by irradiation[5] and, in view of the present work, it would seem expedient to screen natural populations for distorting factors, as any mechanism which would increase the production of males would be most useful to tsetse control programmes which involve the release of sterile males[15].

Giardia excystation can be induced *in vitro* in acidic solutions

MANY vertebrates, including humans, are hosts for the intestinal protozoan parasite, *Giardia*. This genus has a worldwide distribution[1] and in recent years has become an increasingly important public health problem[2–14]. Human infections may be associated with intestinal discomfort, diarrhoea, and malabsorption syndromes[15–17]. The life cycle of *Giardia* is divided into trophozoite and cyst stages. When the cyst is ingested by the host, excystation occurs (trophozoites emerge) and the upper small intestine is colonised. Although research on *Giardia* excystation began nearly 50 yr ago[18,19], conditions for the induction of the process were never defined. We demonstrate here (1) *Giardia* excystation in acidic solutions, (2) the pattern of trophozoite emergence during excystation, (3) a method for routine *in vitro* induction of excystation, and (4) the establishment of *in vitro* axenic cultures from excysted trophozoites.

Cyst-bearing faeces were obtained from humans and animals, purified by a modification of previous procedures[20,21], and stored in water at 8 °C. We attempted to duplicate the conditions to which cysts are exposed *in vivo*. Cysts were exposed to a synthetic gastric juice, transferred into growth medium and examined microscopically. Within 5 min trophozoites were seen excysting (Fig. 1). The escape of the trophozoites resembled the extrusion of a fluid-filled balloon through a small hole in one end of the cyst.

Table 1 Excystation of *Giardia* cysts exposed to inorganic acids at *p*H 2.0

Acid	Mean % excystation ± s.e.m.
HCl	17.4 ± 2.2
HNO_3	12.5 ± 3.0
$HClO_4$	15.5 ± 2.0
H_2SO_4	15 5 ± 2.6
H_3PO_4	19.4 ± 2.8
Water (control, *p*H 6.8)	0.2 ± 0.2

The mean percentage of excystation is the average of 11 trials; an average total of 2,242 cysts were counted in each acid. Mean % excystation for water differs significantly from those of all acids ($P < 0.01$); mean % excystation values for the acids are not significantly different from each other ($P > 0.01$).

To identify the factor(s) responsible for the induction of excystation, complete and component-varied synthetic gastric juice at *p*H 1.6, HSP-3 (see Fig. 1), and water were tested for ability to induce excystation. To count cysts and assess levels of excystation, the following standard procedure was developed. One volume of purified cyst suspension was added to at least 10 volumes of excystation solution (such as synthetic gastric juice, HCl(aq), water), and the mixture incubated at 37 °C for 1 h. The suspension was then centrifuged at 600*g* for 5 min at room temperature, and the pellet resuspended in water and recentrifuged. The pellet was resuspended in 0.5 ml of HSP-3 at 37 °C, and a depression slide chamber filled with the suspension, sealed with a cover glass and paraffin–Vaseline, and incubated

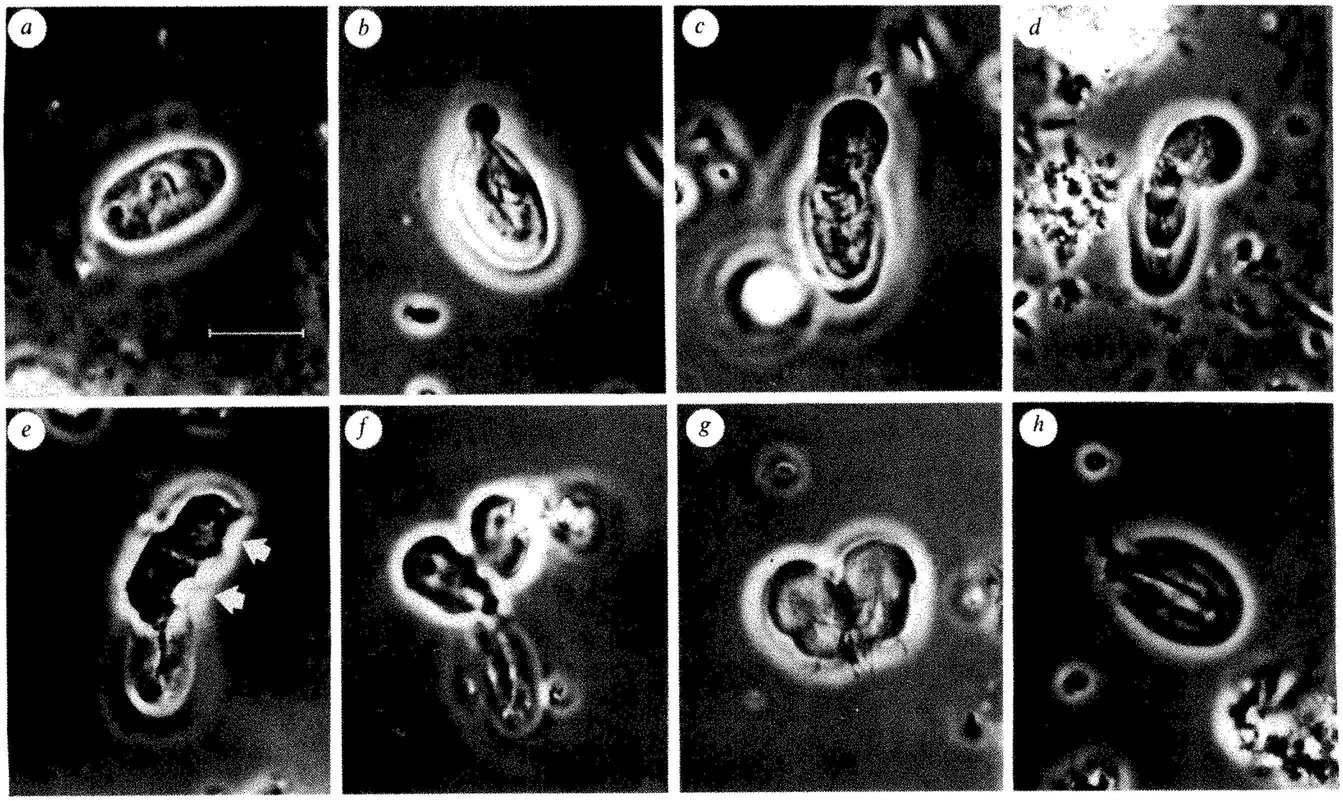

Fig. 1 Representative steps in *Giardia* excystation. *a*, Typical cyst; *b–f*, sequential emergence of trophozoite (arrows in *e* indicate ventral adhesive disks of daughter trophozoites); *g*, excystation completed, division of daughter trophozoites continuing; *h*, empty cyst. The entire process normally requires 5–30 min. Cysts were exposed to 37 °C for 2 h to a synthetic gastric juice containing the following components in aqueous solution: $NaHCO_3$ (25 mN), KCl (12 mN), NaCl (40 mN), $CaCl_2$ (12 mN), and pepsin (1,500 units ml^{-1}; Sigma); final *p*H 1.6 (refs 22, 23). Following exposure to the synthetic fluid, the cysts were transferred into 37 °C HSP-3, a *Giardia* growth medium derived from Meyer's HSP-1 and HSP-2 media[24] with the following formulation: 85 ml Hanks–phytone broth, 20 ml Seitz filter-sterilised heat-inactivated human serum, 7.5 ml NCTC-135 (Gibco), 1.5 ml 1.0 M $NaHCO_3$, 200,000 units potassium penicillin G, 0.01 g streptomycin sulphate and 0.01 g gentamicin sulphate; final *p*H 7.0. Photographs were taken under phase contrast at ×630 on a Zeiss Invertoscope D with Kodak SO-115 film. Scale bar, 10 μm.

inverted at 37 °C for 1 h. The cover glass was scanned systematically at ×300 on an inverted microscope, and cysts and trophozoites were counted. It was found that exposure of cysts to water and HSP-3 yielded negligible ($<0.1\%$) excystation, whereas the other solutions induced 22–26% excystation. Salts and pepsin did not significantly alter the level of excystation in these solutions (Student's *t* test, $P>0.01$), indicating that HCl alone was capable of inducing the process.

Subsequent experiments with HCl(aq) at *p*H values between 0.5 and 6.8 revealed peak percentages of excystation between *p*H 1.3 and 2.7, with a significant drop in excystation above and below peak values ($P<0.01$), and progressively diminishing excystation as the *p*H approached neutrality. These results thus demonstrate a relationship between *p*H and levels of excystation. To determine whether the factor inducing excystation was hydrogen ion, chloride ion, or a combination of the two, several acids were adjusted to *p*H 2.0 and excystation attempted by the standard procedure. Each acid induced essentially identical levels of excystation (Table 1), indicating that the hydrogen ion induced excystation regardless of the counterion.

Giardia excystation therefore seems to be a *p*H-dependent process initiated by acidic conditions encountered during gastric passage. Using the standard excystation procedure with *p*H 2.0 HCl, we have induced excystation of *Giardia* from humans, monkeys, dogs, rats and mice, and have established cultures from excysted trophozoites of cysts obtained from humans and monkeys. These cultures have been maintained for up to 7 months in HSP-3, and most were cultivated axenically from the time of excystation.

This study was supported by research grant R804898020 from the Water Supply Research Division (MERL) US Environmental Protection Agency. We thank Dr Edward Jarroll for suggestions in this research and in the preparation of this paper, and Dr Lynette Feeney-Burns for the use of microscope optics for photographic work.

Arrested proliferation of radial glial cells during midgestation in rhesus monkey

AUTORADIOGRAPHIC analysis using ^{3}H-thymidine labelled DNA demonstrates that some radial glial cells in the fetal monkey cerebrum stop dividing during midgestation. After two months they re-enter the mitotic cycle and become transformed into astrocytes. In their amitotic period, radial glial cells remain stretched across the width of the rapidly expanding telencephalic wall. This is significant because elongated glial fibres may have a role in guidance of neuronal migration[1–3]. The pause in proliferation of radial glial cells could ensure a faithful mapping of the proliferative ventricular surface upon the expanding and convoluted cerebral cortex of primates, including man[3]. Elongated radial glial cells span the distance between the ventricular and pial surface of the developing telencephalon (Fig. 1). Studies using Golgi silver impregnations[4–7], electron microscopy[1,8,9] and immunohistochemistry[10–12] substantiate the glial nature of this transient cell class (for review see refs 12, 13). In the monkey occipital lobe, radial glial cells are present throughout the last two-thirds of gestation[12,14]. The process of transformation of radial glial cells into astrocytes and ependymal cells begins during the first half of gestation and is completed by the second postnatal month[12,14]. However, during midgestation, when neuronal migration is at a peak[15], many radial glial cells remain attached to the ventricular and pial surfaces (Fig. 1); they increase in length, and curve with the expansion and convolution of the cerebral wall[3,12,14]. The present study was undertaken to determine whether such glial cells undergo cell division after attaining their radial configuration.

Brains from 53 monkey fetuses were exposed to a single pulse of ^{3}H-thymidine (^{3}H-TdR) at various stages of gestation as part of study of primate neurogenesis (Table 1)[14–16]. Some fetuses were killed 1 h after injection (column 2, Table 1) to identify the population of actively dividing cells. Others injected at comparable gestational ages were killed at 3,7,14 or 50–60 days later (columns 3,4,5,6 respectively) to determine which cell classes continue to divide (and thereby dilute ^{3}H-TdR) as well as to show any changes in position of non-dividing cells after injection. Finally, some animals were killed several months after birth (column 7). Following fixation, one cerebral hemisphere from each animal was processed for autoradiography[16] and the other was impregnated with the rapid Golgi method[2].

Two populations of cells labelled with ^{3}H-TdR were identified on the basis of their postmitotic behaviour. In monkeys injected at E87 (embryonic day 87) or at E90 and killed 1 h after injection, all heavily labelled cells are found in the ventricular and subventricular zones, the two proliferative areas lining the lateral ventricles (Fig. 2*a*). However, in specimens injected at approximately the same fetal ages, but killed 3 or 7 days after injection, many heavily labelled cells are found in the intermediate zone and in the cortical plate while a certain number of heavily labelled cells remain in the proliferative zones. In animals killed 14 days after injections at E85 or E89, most of the migrating labelled cells have already reached their position in the superficial layers of the cortex[14]; a certain number of labelled cells are, however, still found near the ventricle at this time. In two additional fetuses injected at E85 and E90, but killed after approximately 2 months (E139 and E140, respectively), all migrating cells generated at E85 or E90 have reached their final destinations as neither the intermediate zone nor the deep cortical layers contain labelled cells. The shift in location of heavily labelled cells reflects the well documented pattern of neuronal migration to the neocortex[15]. Again, in these same cases, however, a substantial number of heavily labelled cells persist in the outer part of the subventricular zone and at the ventricular surface. The number of these cells is particularly high in areas underlying large cerebral convolutions where they form wedge-shaped aggregates (Fig. 2*b*).

These observations indicate that during the 2-month interval between ^{3}H-TdR injection and death, a certain number of cells in the subventricular zone do not divide. These non-dividing cells are unlikely to be neurones which in this region complete their proliferation by E100 and reach their final destination before E120 (refs 14, 15). The large pale nuclei of the labelled cells (Fig., 2*c*) have characteristics ascribed to radial glial cells by light and electron microscopy[1]. Furthermore, their location and pattern of distribution in the subventricular zone correspond to the dense concentration of radial glial somas revealed by the Golgi silver impregnation method in the opposite cerebral hemispheres of the same E138–E140 fetuses (Fig. 1*b*).

In specimens injected with ^{3}H-TdR at E140 and killed 1 h later, a substantial number of large pale nuclei of radial glial cells

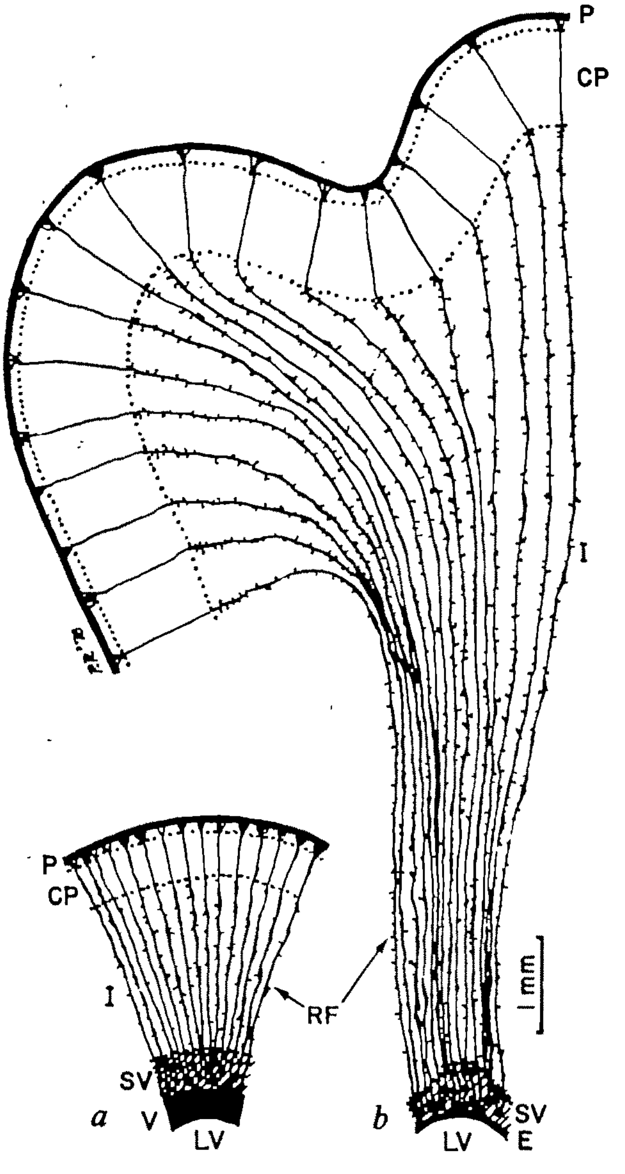

Fig. 1 Semi-schematic drawing of the distribution of radial glial cells in the telencephalon of two monkey fetuses stained with Golgi method. *a*, Dorsal portion of the occipital lobe of 81-d-old fetus (E81); *b*, section from the corresponding region from a fetus at E138. Due to the increased thickness of the cerebral wall and expansion of cortical plate during the intervening period, radial glial fibres that traverse the cerebral wall from the subventricular zone near the lateral ventricle to the pial surface become several times longer and considerably curved. Abbreviations: CP, cortical plate; E, ependyma; I, intermediate zone; LV, lateral ventricle; P, pial membrane, RF, radial fibre; SV, subventricular zone; V, ventricular zone. For more details see refs 1, 12 and 14.

0028-0836/79/0277—0303$01.00

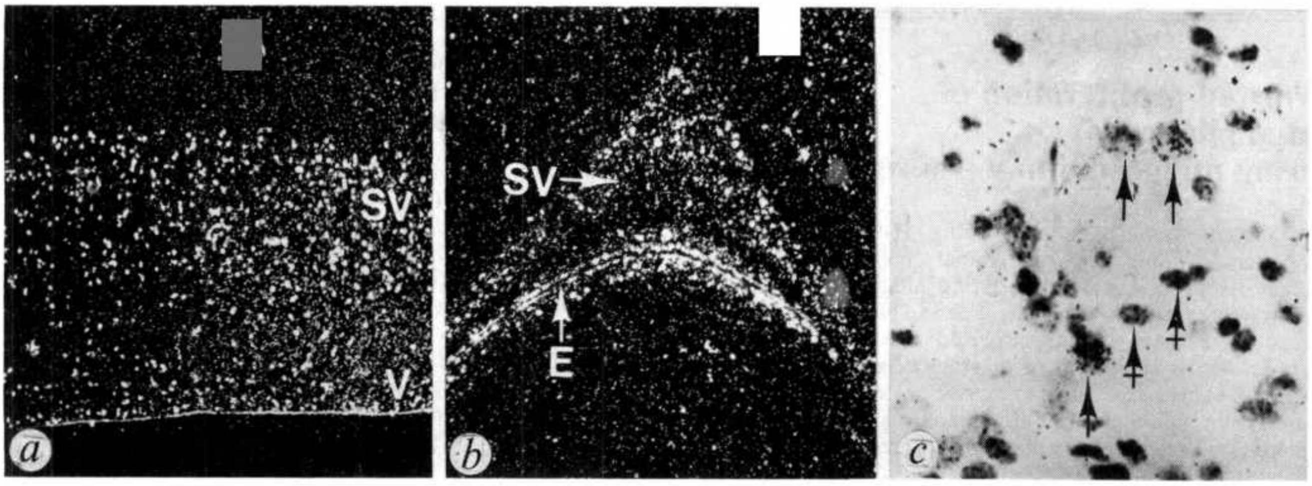

Fig. 2 *a*, Low magnification dark-field illumination photograph of the ventricular (V) and subventricular (SV) zones of the occipital lobe of a monkey fetus injected with ^{3}H-thymidine at embryonic day 90 and killed 1 h later. The confluence of silver gains over radioactive nuclei is such that labelled cells at this magnification appear as solid bright dots. Labelled cells are present in both proliferative zones. *b*, Similar photograph of the corresponding area in monkey fetus injected at E90 but killed at E140. By this fetal age the ventricular zone is exhausted and is replaced with the ependymal layer (E). Although during the 50-day period between injection and death most labelled cells have migrated to the cortex, many heavily labelled cells are still present in the subventricular zone. In the areas subjacent to large convolutions like the one selected here, aggregates of labelled cells form wedges that correspond to the accumulation of radial glial cell somas in Golgi impregnation (for example, see Fig. 1*b*). *c*, Bright-field photograph of large, pale, labelled nuclei (arrows) and unlabelled dark nuclei (crossed arrows) in the subventricular zone of a monkey fetus injected at E85 and killed at E139. The dark unlabelled nuclei apparently represent regular proliferating population of subventricular cells which incorporate ^{3}H-thymidine throughout gestation, but never retain label over long periods.

are labelled in the subventricular zone. However, in monkeys injected at either E90 or E140 but killed postnatally, no labelled cells can be detected in this general region of the occipital lobe except for an occasional ependymal cell. This finding suggests that a certain number of radial glial cells, which have not divided for almost 2 months, re-entered the mitotic cycle around E140 and thereafter divided a sufficient number of times to dilute label beyond detection by autoradiographic method.

Not all radial glial cells in the monkey pass through this amitotic period. It seems that the majority of cells that enter this dormant phase are generated during midgestation. This explains why in specimens killed 14 days after a ^{3}H-TdR injection given earlier or later than the midgestational period (Table 1) only occasional cells in the subventricular zone remain heavily labelled. Evidently, relatively few radial glial cells generated at those fetal ages become non-dividing. Why some radial glial cells enter a mitotically dormant stage, and what induces them to re-enter the mitotic cycle remain to be determined. It is noteworthy that radial glial cells in the amphibian optic tectum can be induced to re-enter their mitotic cycles by transection of the optic nerve[17]. Thus, it is possible that the interaction of the radial fibre with the neuropil below the pial surface may mediate the proliferative activity of glial cell somas situated near the ventricular surface.

The non-dividing cell population in the primate subventricular zone is formed during the period of rapid expansion of the cerebral wall and formation of the cerebral convolutions. The 2-month dormant period during midgestation would explain how some radial glial cells maintain stable positions at both surfaces of the cerebral wall during this period (Fig. 1*a*, *b*). Their amitotic state may be correlated with their proposed function as guides for migration of late-generated neurones[1] and may assure columnar grouping in the cortex of neurones generated at common sites in the proliferative zones[3].

Table 1 Specimens used for the determination of proliferation of glial cells at various stages of development

	Survival after ^{3}H-thymidine injection

Column[1] (age-matched groupings) refers to the time period during which a single intravenous injection of ^{3}H-thymidine (H-TdR) was administered to the pregnant monkey. Gestation in rhesus monkey lasts about 165 days. Animals are killed at various intervals after injection, as indicated by the column headings(2–7). All specimens in any one horizontal row make up one age-matched grouping. E = Embryonic day, P = postnatal day. Each hyphenated set of ages in columns 2–7 represents a single monkey, indicating first the age at time of ^{3}H-TdR injection and then the age at the time of death. The numeral 1 in the 2nd column (for example, E58–58.1) indicates survival time of 1 h following injection at a given embryonic day.

This work, supported by the NIH, was conducted in part at the Department of Neuropathology, Harvard Medical School. Timed pregnant monkeys were obtained from the New England Regional Primate Research Center, Southborough, Massachusetts.

Production of an H-2-related suppressor factor by a hybrid T-cell line

CELL FUSION has been used to study problems in genetics, neoplasia and virology[1]. Its application to immunology was initiated by the experiments of Köhler and Milstein[2], in which it was shown that a myeloma cell (a neoplastic B cell) could be fused with a normal antibody-producing B cell, and that the hybrids continued to secrete the specific antibody of the latter and grew as permanent lines. This type of fusion has since been used to produce homogeneous antibodies to a variety of antigens[3,4]. The same principle can also be applied to T cells, with the aim of producing T-hybrid lines with characteristic T-cell functions, such as cytotoxicity or the ability to help or suppress the responses of other lymphocytes. Recently, fusion of T cells with T-lymphoma cells has been described, leading to the establishment of lines carrying markers characteristic of the normal T-cell partner[5–7], and some lines with T-cell activities have been reported[8,9]. We describe here the production of a hybrid line which exhibits a characteristic T-cell function, namely, specific suppression of the antibody response. The hybrid cells produce a suppressor molecule or 'factor' which binds to an antigen, sheep red blood cells (SRBC), and specifically suppresses the antibody response to this antigen *in vitro*. The factor is non-immunoglobulin, but carries determinants of the H-2 complex.

Hybridisation was carried out using the thymoma line BW 5147 (derived by Dr R. Hyman), which lacks the enzyme hypoxanthine guanine phosphoribosyl transferase (HGPRT) and consequently can be killed by medium containing HAT (hypoxanthine, aminopterin, thymidine)[10]; 5×10^7 thymoma cells were fused with 2×10^8 spleen cells of C57BL/10ScSn mice which had been immunised 5 d previously by injection of 0.1 ml 10% SRBC. Polyethylene glycol was used as fusing agent, after the method of Pontecorvo[11] as modified by Goldsby *et al.*[5]. After fusion, cells were seeded at about 10^6 per well in 0.2-ml volumes in 96-well culture plates (Falcon) and cultured in selective medium, that is, RPMI 1640 supplemented with 15% fetal calf serum and HAT. After 3 weeks, 58 of 214 wells seeded showed positive growth, indicating that they contained hybrid (HGPRT-positive) cells; their contents were transferred in 1-ml volumes to 24-well culture plates (Linbro) for continued growth. Further cloning of these cells was not carried out. Karyotypic analysis of several lines showed that the average chromosome number was between the normal mouse diploid (40) and tetraploid, and was in all cases higher than that for BW 5147, which has a chromosome number close to 40.

Supernatants of growing hybrid lines were tested for their ability to suppress primary antibody responses *in vitro* of either mouse spleen cells or mouse thoracic duct lymphocytes (TDL) against SRBC and other antigens. Although most supernatants, including that of BW 5147 cells, failed to influence the antibody response, a striking suppressive effect was obtained with that of a line designated A1. Table 1 shows that the A1 supernatant produced suppression of about 90% of the primary (IgM) response of spleen cells to SRBC but did not suppress the response to donkey red blood cells (DRBC). Moreover, the suppressive effect could be abolished by absorption of the A1 supernatant with SRBC, not with red cells of other species.

Using mouse TDL in a microculture system[12], the supernatant produced complete suppression of the response to SRBC and could be titrated to an endpoint of 50% suppression at a dilution

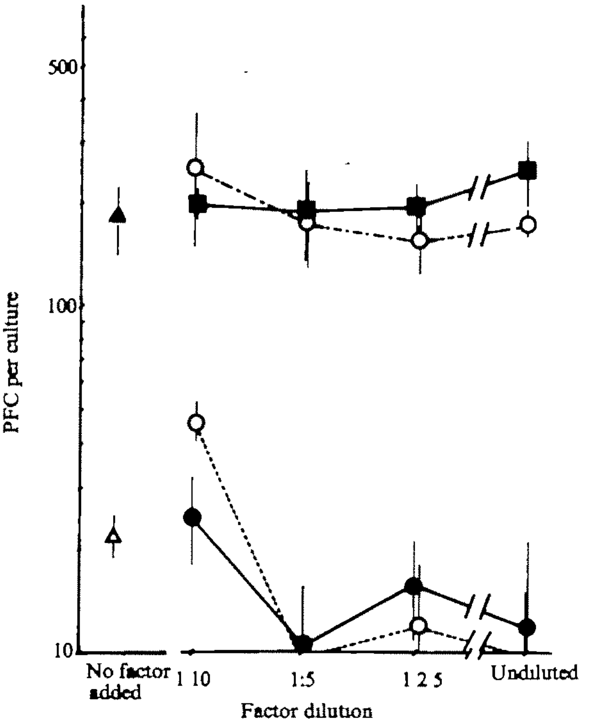

Fig. 1 Suppression of the antibody response to SRBC *in vitro* by supernatant factor of the A1 hybrid line. The figure shows the primary (IgM) antibody response to SRBC of mouse thoracic duct lymphocytes (TDL) in the presence of supernatant (factor) of A1 (●——●), A1 supernatant after absorption by SRBC (○-·-·-○) or by DRBC (○----○), or supernatant of another line, A3, as control (■——■). The level of response in the absence of added supernatant is shown (▲), as is the background in the absence of SRBC (△). The method will be described in detail elsewhere[12] In brief, 0.5×10^6 TDL of C57BL/10ScSn mice (an overnight collection of mouse thoracic duct cannulated according to ref 20) were incubated with 1×10^6 SRBC and 25 µl of the factor to be tested (or a dilution thereof) in a total culture volume of 225 µl, in round-bottomed microtitre trays (Linbro IS-MRC-96TC) under 5% CO_2/air at 37 °C. The culture medium was RPMI 1640 supplemented with 10% fetal calf serum, 2 mM glutamine, 100 U ml^{-1} penicillin–streptomycin and 1×10^{-5}M 2-ME. After 4 d, cells in each well were collected and direct plaque-forming cell (PFC) numbers determined[19]. Each point is the geometric mean of triplicate cultures ±s.d.

Table 1 Suppression of the primary antibody response *in vitro* by supernatant of the T-hybrid line A1

Supernatant	Primary PFC response to: SRBC	% Suppression	DRBC	% Suppression
None	3 29(1960) ± 0.05		3.06(1160) ± 0.07	
BW 5147	3.25(1760) ± 0.03	10	3.09(1240) ± 0.04	0
Line A3	3.31(2040) ± 0.06	0	3.01(1030) ± 0.05	11
Line A1	2.24(174) ± 0.13	91	2.99(986) ± 0.05	15
A1 after absorption by:				
SRBC	3.24(1720) ± 0.07	12	ND	
DRBC	2.45(280) ± 0.15	86	ND	
Ox RBC	2.62(420) ± 0.10	79	ND	
anti-mouse antiserum	2.53(338) ± 0.20	83	ND	
anti-IgM	2.19(158) ± 0.19	92	ND	
anti-IgG$_{2a}$	2.48(300) ± 0.13	85	ND	
anti-IgG$_{2b}$	2.56(360) ± 0.22	82	ND	
anti-IgA	2.31(204) ± 0.24	89	ND	
anti-H–2^k	2.28(193) ± 0.23	90	ND	
anti-H–2^b	3.33(2130) ± 0.03	0	ND	

Results are primary IgM plaque-forming cell (PFC) responses of spleen cell cultures. Spleen cells of non-immunised C57BL/10ScSn mice were suspended at a density of 6×10^6 per ml and incubated with 50 µl 1% red cells in 1-ml volumes in culture tubes (Falcon) for 5 d, as described by Fridman and Golstein[18]. The culture medium was RPMI 1640 with addition of 2 mM glutamine, 1 mM pyruvate, 100 U ml^{-1} penicillin–streptomycin, 10% fetal calf serum, 1% horse serum, 5×10^{-5} M 2- mercaptoethanol (ME), and tubes were incubated under 5% CO_2/95% air. At the start, 100 µl of hybrid supernatant, taken after 48 h incubation of 5×10^5 hybrid cells in fresh medium (RPMI 1640, 15% fetal calf serum, glutamine, pyruvate, antibiotics as above) was added. Direct PFC were enumerated on day 5 in agar-free chambers[19]. Results as PFC per 10^6 viable cells, expressed as $\log_{10}$ geometric means of quadruplicate cultures (anti-log in parentheses) ± standard deviation. For absorption by red cells, 1 ml A1 supernatant was mixed with 0.1 ml 50% red cells for 1 h at room temperature and then centrifuged. For other absorptions, supernatant was passed over immunoadsorbents prepared by conjugation of antisera to CNBr-activated Sepharose (Pharmacia). Anti-mouse antiserum was raised in sheep against whole mouse serum; the specific anti-immunoglobulin reagents were also sheep anti-mouse and were anti-MOPC 104E(IgM, λ), anti-Adj PC5 (IgG$_{2a}$, κ), anti-MOPC 141 (IgG$_{2b}$, κ) and anti-MOPC 315 (IgA, λ). Anti-H–2^k was C57Bl/10 anti-C3H; anti-H–2^b was C3H anti-C3H.B10. Line A3 was a non-suppressor line from the same hybridisation, as negative control. DRBC, donkey red blood cells. ND, not done Background (antigen omitted from culture): 1.89(79) ± 0.30 (SRBC), 1.60(40) ± 0.33 (DRBC).

Table 2 Suppression by T-hybrid line Al supernatant of the primary response of C57BL/10 thoracic duct lymphocytes to SRBC and TNP$_{10}$-SRBC *in vitro*

Antigen	Hybrid supernatant	Undiluted	Dilution of supernatant 1:2.5	1:5	1:10	1:20
SRBC	Line A3	2.32(209) ± 0 04	ND	ND	ND	ND
	Line Al	0.30(2) ± 0.32	0.38(2) ± 0 29	1.52(33) ± 0.19	1.88(76) ± 0.13	2.27(186) ± 0 15
	Medium control		2.36(230) ± 0 04			
	Background		1.13(13) ± 0.34			
TNP$_{10}$-SRBC*						
	Line A3	2.15(140) ± 0.20	ND	ND	ND	ND
	Line Al	0.50(3) ± 0.33	0.30(2) ± 0.38	1.13(13) ± 0.35	1.52(33) ± 0.18	2.12(131) ± 0.08
	Medium control		2.09(123) ± 0.04			
	Background		0.38(2) ± 0.22			

Cultures of TDL were set up as described in the legend to Fig. 1, the initial cell number being 0.5×10^6 per culture. Either SRBC or trinitrophenylated SRBC (TNP$_{10}$-SRBC, ref. 21) was added as antigen (1×10^6 per culture), together with 25 µl of hybrid supernatant or a dilution thereof. After 4 d, direct PFC were measured against SRBC or TNP$_{10}$-DRBC* Results as $\log_{10}$ geometric means PFC per culture (anti-log in parentheses) ± standard deviation. Line A3 was a non-suppressor line used as negative control. As medium control, normal medium was used instead of hybrid supernatant, and for background values, antigen was omitted from the cultures. ND, not done.

Table 3 Binding of anti-immunoglobulin and anti-H–2 antibodies to SRBC treated with supernatant of T-hybrid lines

Hybrid supernatant	Binding (c.p.m.) Anti-Fab	Anti-μ	Anti-H–2^b	Anti-H–2^k
None	73 ± 14	93 ± 20	86 ± 16	107 ± 17
Line A3	46 ± 9	81 ± 19	114 ± 21	88 ± 23
Line A1	58 ± 10	70 ± 12	701 ± 66	65 ± 11
Positive controls (anti-SRBC antiserum)		anti-Fab: 4,330 ± 263 anti-μ . 3,720 ± 186		
c.p.m. of ^{125}I-reagents		anti-Fab: 15,500 ± 294 anti-μ · 14,200 ± 318		
Machine background		35 ± 4		

100 µl of each supernatant was reacted with 25 µl 10% SRBC; cells were washed 3 times, then incubated with 25 µl of ^{125}I-labelled sheep anti-mouse Fab or sheep anti-mouse μ, or with 25 µl undiluted anti-H–2 antisera followed, after washing, by the ^{125}I-anti-Fab reagent. As positive controls SRBC were treated with mouse anti-SRBC antiserum followed after washing by the labelled anti-Fab or anti-μ. After further washing, the c.p.m. bound to red cells were counted. Anti-mouse Fab was raised in sheep against the Fab fragment of Adj PC5 (IgG$_{2a}$, κ), anti-μ was sheep anti-MOPC 104E (IgM, λ) absorbed with λ light chains; anti-H–2 antisera were as in Table 1. Results as means of duplicate tests ± standard deviation. Line A3 was a negative control supernatant; supernatants of 36 other lines also gave negative results.

of 1 : 20 (a final dilution in the culture of 1 : 180), as shown in Figs 1 and 2. Here too, absorption of the supernatant with SRBC removed its suppressive activity. However, a nonspecific suppression of TDL was evident at high concentrations of supernatant, when it was possible to suppress the responses to trinitrophenylated (TNP)–DRBC or TNP–ovalbumin as well as to SRBC (Fig. 2). Nevertheless, specificity for SRBC appeared as the supernatant was diluted beyond 1 : 2.5. Although the ability of the A1 supernatant to suppress the anti-TNP response to TNP–DRBC was clearly weak (Fig. 2), it suppressed the response to TNP in the form of TNP–SRBC as effectively as the response to SRBC itself (Table 2). Thus, suppression extended to haptens attached to SRBC and was evidently carrier specific. To date, we have found the supernatant to be equally effective on C57BL/10 (H-2^{b}), CBA (H-2^{k}) and BALB/c (H-2^{d}) TDL. The production by the A1 line of a suppressor factor with specificity for SRBC proved to be a stable characteristic of the line and could be demonstrated with supernatants obtained after passaging the cells for 7 months in culture.

The nature of the A1 suppressor molecule was explored by passing the supernatant over immunoadsorbents to which anti-mouse immunoglobulin (mIg) or mouse alloantisera had been chemically coupled. Table 1 shows that anti-mIg adsorbents were unable to remove the suppressive activity. In contrast, this activity was lost if the A1 supernatant was passed over certain anti-H-2 adsorbents; specifically, immobilised antisera against the haplotype of the primed spleen cells used in the fusion (H-2^{b}) were able to remove the A1 molecule, whereas those reacting with the haplotype of the thymoma (H-2^{k}) could not. Similarly, it was shown that the molecules in the A1 supernatant binding specifically to SRBC carried H-2 determinants and were non-Ig. Table 3 shows that SRBC treated with the A1 supernatant failed to bind radiolabelled anti-mIg reagents (anti-Fab, anti-μ), but did bind anti-H-2^{b} antisera (detected by subsequent binding of radiolabelled anti-mIg). In other experiments this reaction was shown to be specific for SRBC. These results indicate that the A1 suppressor factor is an SRBC-binding molecule which is non-Ig and carries determinants coded in some portion of the H-2 complex. The structure of this molecule was explored further after radiolabelling, as described in the accompanying paper[13].

Surface antigens of the A1 line were detected using antisera against H-2, mIg and Thy-1. A1 cells expressed the H-2 antigens of both BW 5147 and C57BL/10 parent cells (H-2^{k} and H-2^{b}) and both Thy-1 alleles (Thy-1.1 and Thy-1.2, respectively). A1 and all other T-hybrid lines failed to react with a variety of anti-mIg reagents, including radiolabelled sheep anti-mouse Fab and anti-μ, and fluoresceinated anti-whole mouse Ig. Similar results have been found by others[6,7] and suggest either that BW 5147 does not hybridise with B cells or that Ig synthesis is always repressed by BW 5147 genes. The A1 line formed rosettes with SRBC, indicating the presence of receptors for SRBC at the cell surface. However, we have found formation of rosettes with red cells of certain species, particularly bovine and sometimes sheep, to be a property of many T-hybrid lines, but not of BW 5147 itself. It is also seen with lines formed by fusion of myelomas with B cells, and in the majority of cases it is apparent that rosette formation is unrelated to the antigen specificity of the lines; its significance is not yet clear. Although many T-hybrid lines bind heterologous red cells, only A1 has so far been found to release soluble material reacting with red cells. (The phenomenon of rosette formation by hybrid lines will be published elsewhere[14].)

The results described here show that it is possible to produce by fusion a hybrid line which retains a functional characteristic of a normal T-cell population after antigen stimulation. This and similar lines[8,9] promise to be of considerable value in studying the properties of the molecules produced by normal T cells, including receptors for antigen. From the characteristics of the A1 line, we suggest that the normal parent cell in the fusion may have been an SRBC-specific suppressor T cell. Thus, the suppressor molecule it releases resembles the antigen-specific factors which have been found in cultures or extracts of antigen-stimulated T cells and which can replace T cells in regulation of the antibody response[15,16]. Although the A1 line has not yet been cloned, it is likely that the factor it produces is homogeneous and recognises a single type of determinant on SRBC. Nevertheless, it is able to suppress the anti-SRBC response completely and can also inhibit the response to a hapten coupled to SRBC. Thus, it seems unlikely that its suppressive action is due solely to blocking of antigenic determinants on the red cell surface. A direct effect on lymphocytes is indicated by the apparently nonspecific suppression which A1 supernatants produce when at sufficiently high concentration (Fig. 2) and by more recent observations we have made which indicate that the A1 factor is absorbed by B cells in the absence of SRBC[17]. Our hypothesis is that the factor reacts with both B lymphocytes and SRBC and that its greater effectiveness against the latter than against other antigens is due to its binding site for SRBC, which causes it to be concentrated at the surface of SRBC-binding B cells.

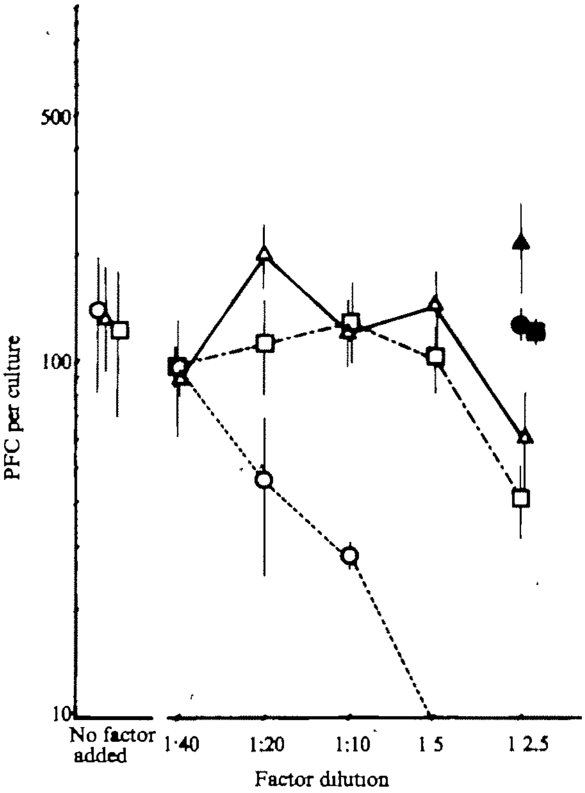

Fig. 2 Specificity of suppression of the antibody response by A1 supernatant factor. Culture conditions were as described in Fig. 1, using in this experiment TDL of CBA mice Antigens added to the cultures were 1×10^{6} SRBC (○), 1×10^{6} TNP$_{10}$–DRBC (△) or 0.125 μg TNP$_{5}$–ovalbumin (□), together with 25 μl of A1 factor or a dilution thereof (trinitrophenylation of DRBC was according to ref. 21). PFC were determined against SRBC or TNP$_{10}$–SRBC[21] after 4 d. Controls are shown in which supernatant of the A3 line was used instead of A1 (closed symbols) or in which no supernatants were added.

An important point of similarity with other specific T-cell factors is that although the A1 factor binds specifically to SRBC, it lacks Ig determinants and carries antigens coded by the H-2 complex[15,16]. Until now the main drawback to determination of the structure of antigen-specific T-cell factors has been the very small amount of material available, a problem which is overcome by the release of factors by permanent hybrid lines. In the accompanying report, some molecular characteristics of the suppressor factor produced by the A1 line are described.

We thank Dr P. Démant for alloantisera, Dr D. Antczak for TNP$_{5}$-ovalbumin, Mr J. Herbert for sheep anti-mouse Ig antisera, Mr N. Richardson for iodinated anti-mouse Ig reagents and Dr J Howard for helpful suggestions. This work was supported in part by MRC grant G 975/871/C and USPHS grant AI-13162.

Structure of an antigen-specific suppressor factor produced by a hybrid T-cell line

THE preceding report[1] described the production by the hybrid T-cell line A1 of a suppressor factor with specificity for sheep red blood cells (SRBC). The factor, which binds specifically to SRBC and suppresses the antibody response to this antigen in culture, does not react with anti-mouse immunoglobulin (mIg) reagents, but is removed by mouse alloantisera (anti-H-2). In these respects it resembles the antigen-specific T-cell factors which have been obtained from T cells after stimulation by antigen and which play an important part in regulation of the antibody response[2,3]. We report here our study of the structure of the A1 suppressor molecule by incorporation of ^{3}H-leucine, followed by SDS–polyacrylamide-gel electrophoresis (SDS–PAGE). The molecule seems to be composed of two types of polypeptide chain in noncovalent association, a large chain of molecular weight 85,000 and a small chain of 25,000. The MW of the native molecule is about 200,000. The isolated large chain binds to SRBC. The H-2 determinants are apparently present on the small chain.

The origin of the A1 line, as a result of fusion between the AKR (H-2^k) thymoma line BW 5147 and spleen cells of a C57BL/10ScSn (H-2^b) mouse injected with SRBC, and the properties of the supernatant of the line, have been described in the preceding report[1]. The molecular weight of the A1 suppressor factor was determined by gel filtration on an ultrogel AcA 34 column (LKB), eluted fractions being tested for ability to suppress the primary response of murine thoracic duct lymphocytes against SRBC, as previously described[1]. The maximum suppressor activity emerged in the same fractions as a 7S IgM marker, indicating an apparent MW of about 200,000. No activity was found in fractions corresponding to MWs of less than 150,000 (Table 1).

Internal labelling of the A1 factor was achieved by allowing the cells to incorporate ^{3}H-leucine. Cells at a density of 2×10^6

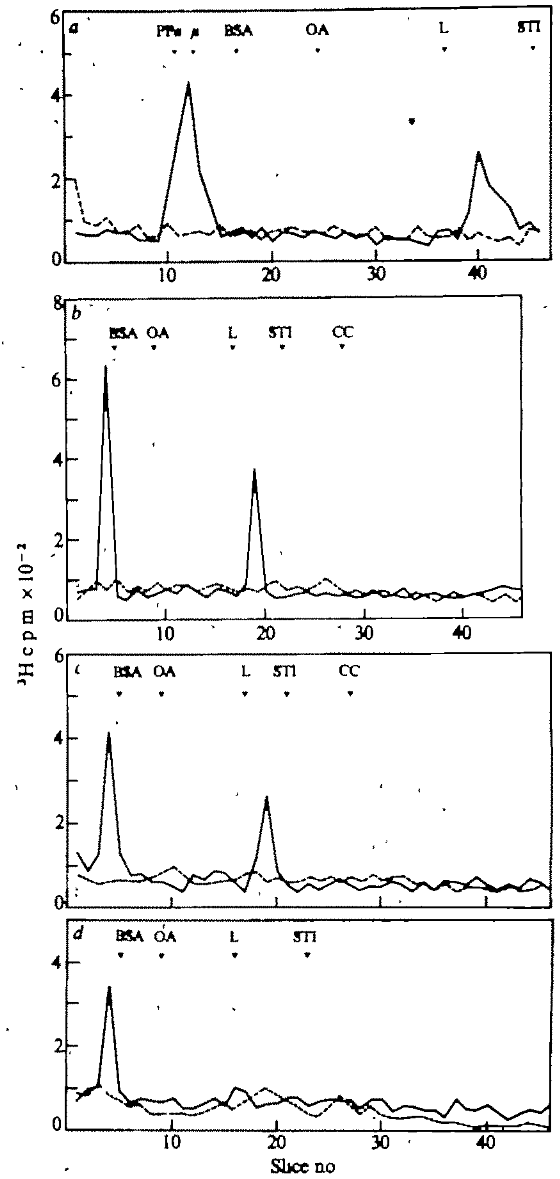

Fig. 1 SDS–PAGE profiles of SRBC-binding factor produced by the A1 hybrid line. *a*, Electrophoresis on 10% polyacrylamide gel of SRBC treated with ^{3}H-leucine-labelled supernatant of A1(——) or BW 5147(– – –). 100 µl of the labelled supernatant was incubated with 10 µl packed SRBC for 1 h at room temperature. The red cells were then washed 3 times, dissolved in SDS sample buffer in the presence of 2-ME and phenylmethanesulphonyl fluoride, heated at 100 °C for 2 min and run according to the discontinuous system of Laemmli[4]. Markers were phosphorylase *a* (PP*a*, MW 92,000), heavy (µ) and light (L) chains of MOPC 104E, bovine serum albumin (BSA, MW 68,000), ovalbumin (OA, MW 45,000), and soybean trypsin inhibitor (STI, MW 21,000). *b*, Electrophoresis on 15% polyacrylamide gel of SRBC treated with ^{3}H-leucine-labelled supernatant of A1(——) or BW 5147(– – –) Red cells prepared as in *a*. Markers as in *a* with addition of cytochrome *c* (CC, MW 12,500). *c*, Electrophoresis on 15% polyacrylamide gel of SRBC treated with ^{3}H-leucine-labelled supernatant of A1 after precipitation by anti-H–2^k(——) or anti-H–2^b(– – –) antisera and sheep anti-mouse whole serum. 100 µl of the labelled supernatant was mixed with 20 µl undiluted anti-H–2^k (C57BL/10 anti-C3H) or anti-H–2^b (C3H anti-C3H.BIO) antiserum, followed after 1 h by 250 µl sheep anti-mouse whole serum. After removal of the precipitate 10 µl packed SRBC was added to the supernatant and after 1 h at room temperature the red cells were washed and run on SDS–PAGE as in *b*. Markers as above. *d*, Electrophoresis on 15% polyacrylamide gel of fixed SRBC treated with NP40 extracts of ^{3}H-leucine-labelled A1 cells (——) or BW 5147 cells (– – –). 10 µl packed glutaraldehyde-fixed SRBC was added to 30 µl NP40 extract (see text); after 1 h at room temperature the red cells were washed and run on SDS–PAGE as in *b*. Markers as above.

Table 1 Determination of molecular weight of A1 suppressor factor by gel filtration

Fraction no.	PFC	% Suppression
21	2 21(162) ± 0.08	0
23	2.29(195) ± 0.10	0
25	1.70(50) ± 0.18	71
27	1.02(10) ± 0.28	99
29	1.08(12) ± 0.15	97
31	1.30(20) ± 0.25	92
33	2.06(115) ± 0.11	25
35	2.20(160) ± 0.18	0
37	2.14(138) ± 0.12	9
39–61	No suppression in any fraction	
Medium control	2.18(151) ± 0.10	
Background	0.90(8) ± 0.25	

5 ml of A1 supernatant was concentrated to 0.8 ml, centrifuged to remove aggregates, and the sample applied to an ultrogel AcA 34 column (dimensions 93 cm × 2 cm^2). The column was run in phosphate-buffered saline. 3-ml fractions were collected and alternate fractions from no. 21 onwards were tested for ability to suppress the primary response to SRBC *in vitro* of mouse (C57BL/10) thoracic duct lymphocytes, as previously described[1]. Markers for MW were run separately and were shown reproducibly to emerge maximally in the following fractions: 23, blue dextran (exclusion volume); 27, 7S IgM (partial reduction product of MOPC 104E, MW 216,000); 37, μ chain of MOPC 104E (MW 80,000); 41, bovine serum albumin (MW 68,000); 44, ovalbumin (MW 44,000), 47, light (λ) chain of MOPC 104E (MW 28,000); 61, phenol red. PFC results as $\log_{10}$ PFC per culture (anti-log in parentheses) ± standard deviation. For medium control, normal medium was used instead of fraction, and for background values, SRBC were omitted from culture.

per ml were incubated for 20 h in leucine-free RPMI 1640 medium (free of fetal calf serum), supplemented with 100 μCi per ml of ^{3}H-leucine (Amersham). The labelled supernatant was allowed to react with red cells of various species and was found to bind optimally to SRBC, with some detectable binding to rabbit red cells, but none to mouse, ox or donkey (Table 2). This binding did not occur if the labelled supernatant was first treated with anti-H-2^b antiserum, followed by precipitation with sheep anti-mouse whole serum; in contrast, anti-H-2^k antiserum failed to remove the binding activity in this test, as shown in Table 1. (H–2^b is the haplotype of the primed spleen cells used in the fusion; H–2^k is that of the thymoma cells to which they were fused.) Precipitation with anti-mIg reagents, including anti-IgM (MOPC 104E) and anti-IgD (Sera Labs), or with sheep anti-mouse whole serum, also failed to remove the SRBC-binding molecule from the tritiated A1 supernatant.

SRBC which had been allowed to bind the tritiated A1 factor were washed, dissolved in SDS in reducing conditions and electrophoresed on 10% and 15% polyacrylamide gels[4] (Fig. 1*a*, *b*). This revealed two polypeptide chains, a large chain which showed an apparent MW of about 85,000 and a smaller chain of about 25,000. Similar gel profiles were obtained in the absence of 2-mercaptoethanol (ME), indicating that the chains are not linked by disulphide bonds. If the A1 supernatant was first reacted with anti-H-2^b antiserum, followed by precipitation with sheep anti-mouse whole serum, both chains were removed; reaction with anti-H-2^k antiserum and sheep anti-mouse whole serum failed to precipitate either chain (Fig. 1*c*). From these observations, it seems that the SRBC-binding molecule produced by the A1 hybrid line is composed of two types of polypeptide chain, one or both of which carries determinants coded by genes in the H–2 complex of the primed spleen cells used in the fusion.

Attempts were then made to identify the SRBC-binding molecule in lysates of the labelled A1 cells. After incorporation of ^{3}H-leucine as above, A1 cells were dissolved in the non-ionic detergent Nonidet P40 (NP40). Nuclei were spun down and the solubilised material tested first for binding to glutaraldehyde-fixed red cells (the fixation was such as to prevent lysis in NP40, but leave red cell antigens available, as evidenced by binding of anti-red cell antibodies). Table 3 shows that the NP40-extracted material from A1 bound to SRBC specifically; however, binding was not appreciably reduced by precipitation of the extracts with anti-H–2 antisera. Furthermore, when analysed by SDS–PAGE, the NP40 lysate of A1, absorbed onto fixed SRBC, showed a single peak of radioactivity, corresponding to the large chain of the A1 supernatant molecule (Fig. 1*d*). This peak persisted after precipitation of the lysate with anti-H-2^b antiserum and sheep anti-mouse whole serum. These findings imply that the H–2 determinants of the supernatant factor secreted by A1 are associated only with its smaller polypeptide chain. The absence of the latter from NP40 extracts suggests that the large and small chains may be assembled only when the molecule is secreted and that within the cytoplasm they may exist as separate pools.

Table 2 Binding to red cells of supernatant of T-hybrid line A1 after incorporation of ^{3}H-leucine

Supernatant	Treatment	Sheep	c.p.m. bound by red cells of Mouse	Ox	Rabbit	Donkey
BW 5147	—	82	71	64	63	87
A1	—	640	80	83	240	106
A1	Anti-H–2^b precipitation	166				
A1	Anti-H–2^k precipitation	519				

50 μl of supernatants of the A1 hybrid line or of the thymoma BW 5147, after labelling with ^{3}H-leucine as described in the text, were reacted with 10 μl 10% red cells of the species shown for 1 h at room temperature. The red cells were then washed 3 times and counted in a β-counter. Where indicated, A1 supernatant was precipitated, before the binding assay, by addition of 10 μl undiluted anti-H–2 antiserum to 50 μl supernatant, followed after 1 h by 150 μl sheep anti-mouse whole serum. Anti-H–2^b antiserum was C3H anti-C3H.B10; anti-H–2^k was C57BL/10 anti-C3H. Results are means of duplicate tests.

Table 3 Binding to red cells of NP40 extracts of T-hybrid line A1 after incorporation of ^{3}H-leucine

Extract	Treatment	c.p.m. bound by red cells of: Sheep	Ox	Donkey
BW 5147	—	125	85	135
A1	—	520	116	143
A1	Anti-H–2^b precipitation	405	91	76
A1	Anti-H–2^k precipitation	476	82	89

Hybrid line A1 and thymoma BW 5147 were internally labelled by growth in ^{3}H-leucine as described in the text. Extracts were prepared by dissolving 2×10^7 labelled cells in 500 μl 1% NP40 and aliquots of 25 μl were tested for binding to 50 μl 2% red cells previously fixed in 0.25% glutaraldehyde. Precipitation with anti-H–2 antisera was as in Table 2. Results are means of duplicates.

Although the structure of the A1 suppressor factor is reminiscent of 7S immunoglobulin, the chains are not disulphide linked and moreover lack the antigenic characteristics of either Ig heavy or light chains. The only antigenic determinants so far detected on the suppressor are those of the H–2 complex. The observations with labelled molecules extracted from A1 cells with NP40 indicate that the large chain is able to bind specifically to SRBC, but lacks both Ig and H–2 determinants. We conclude, therefore, that the H–2 specificities detectable on the secreted factor are probably associated with the 25,000-MW chain. As yet there is no evidence that the latter has a role in binding to SRBC.

The similarity in general properties between the A1 factor and antigen-specific T-cell factors has already been noted, in particular, the features of specific antigen binding together with H–2 association. A notable difference is the molecular weight, as the MWs of the factors obtained by sonication of suppressor T cells[3] or from T-cell supernatants[2] have been found to lie in the range of 35–55,000. It may be that the MWs of factors reported hitherto have been underestimated, perhaps due to partial proteolytic digestion before sizing.

The indication that H-2 specificities are carried by the smaller chain of the A1 factor is of particular interest. We have not yet mapped the sub-region of H-2 coding for this chain, but antigen-specific suppressor factors obtained from T cells[3] or from another T-hybrid line[5] carry Ia determinants of the I-J sub-region. The size of the small chain of the A1 factor, about 25,000, would be consistent with an origin in the I region, as mouse Ia molecules have chains of MWs about 25,000 and 35,000 (ref. 6). Although the large chain of the factor carries a binding site for SRBC, it may be the rôle of the H-2-derived chain to provide the suppressive activity of the factor. The importance of the binding site would then be to ensure a high local concentration of factor at the surface of antigen-binding lymphocytes and hence specificity of suppression[1].

We thank Dr P. Démant for alloantisera and Mr J. Herbert for sheep antisera.

Crossreacting determinants in the C-terminal region of trypanosome variant surface antigens

ANTIGENIC variation seems to be the primary mechanism enabling the pathogenic African trypanosomes to evade the immune systems of their mammalian hosts (reviewed in refs 1–3). Antigenic variation is mediated through sequential expression of an extensive repertoire of variant surface glycoproteins (VSGs). Several VSGs have been purified from cloned variants of *Trypanosoma brucei*[4,5]. The diversity in amino acid composition, conformational features[6] and N-terminal amino acid sequences[7] implies extensive structural diversity in VSGs so far studied. Earlier studies failed to identify immunological crossreactivity between VSGs when purified or whilst on the surface of living trypanosomes. Some time ago, Dr Frans van Knapen and I, while performing enzyme-linked immunoabsorbant assays, were puzzled to observe extensive crossreactions between two purified VSGs and a wide range of antisera to different trypanosome species (unpublished experiments). A recent study by Barbet and McGuire[8] provided additional evidence for the presence of strongly crossreacting determinants on a wide range of VSGs. In several cases, the VSGs examined by Barbet and McGuire originated from clones which I previously prepared and examined. I have therefore re-examined several VSGs and their corresponding antisera by radioimmunoassay. The results reported here are consistent with those of Barbet and McGuire. Additional observations suggest that the crossreacting determinants are located towards the C-terminal end of the VSG.

As no rational basis for classification of VSGs exists, they are referred to by the stock numbers of the trypanosome clone from which they were obtained, as previously described[4]. Figure 1 shows the titration, by radioimmunoassay, of antisera of seven specificities against four variant antigens purified from randomly selected clones of *T. brucei* strain 427 (ref. 4). It is clear that VSGs 55, 221 and 121 may be substantially precipitated by certain heterologous antisera; VSG 55 (Fig. 1*a*) is most

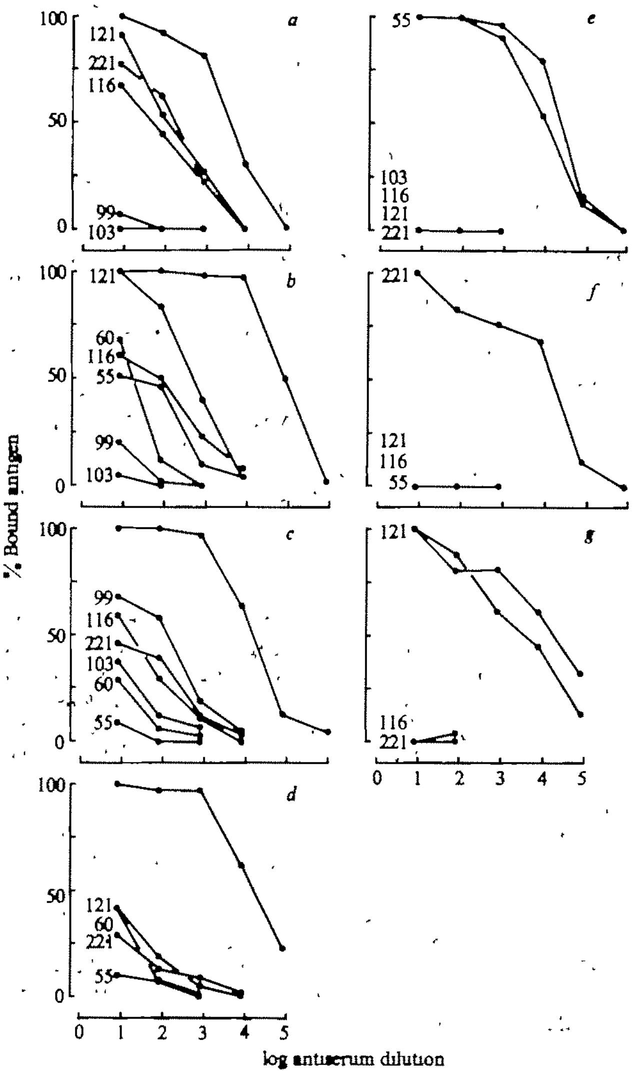

Fig. 1 Immunoprecipitation of four VSGs and three N-terminal tryptic fragments by homologous and heterologous antisera. The antigens are VSGs 55 (*a*); 221 (*b*); 121 (*c*); 116 (*d*), and N-terminal fragments from VSGs 55 (*e*); 221 (*f*); and 121 (*g*). ○, Homologous antisera; ●, heterologous antisera. Antigens were labelled by the chloramine-T method to a specific activity between 1,000 and 10,000 c.p.m. per ng. Antisera were raised in 2–4-kg New Zealand White rabbits by primary subcutaneous injection at four sites of a total of 1 mg purified VSG in an emulsion of 0.2 ml saline per 0.2 ml Freunds complete adjuvant. Two further subcutaneous injections of 0.5–1 mg VSG in saline were given at 10-d intervals. Sera were obtained 7–10 d after the third or subsequent injections of antigen and were lyophilised and stored under nitrogen at −20 °C. Radioimmunoassay was performed by incubating (2 h at 37 °C in a total volume of 0.065 ml phosphate-buffered saline[12] containing 4 mg ml^{-1} bovine albumin) 1 ng antigen with antisera dilutions prepared in appropriate dilutions of normal rabbit serum to maintain a constant amount of rabbit serum in each assay. Antigen–antibody complexes were precipitated with goat anti-rabbit IgG (Miles) and counted. Antiserum dilution is plotted against the percentage of bound antigen, after correction for nonspecific binding, taking the maximal precipitation by homologous antiserum as the 100% value. Maximal precipitation was generally equivalent to 95–100% of acid-precipitable radioactivity.

effectively precipitated by heterologous antisera 116, 121 and 221. However, an eightfold dilution was required to approach 100% precipitation. At this concentration neither antisera 99 nor 103 caused significant precipitation; 121 was the only heterologous antiserum which totally precipitated VSG 221 (Fig. 1*b*). The concentrations of heterologous antisera required to precipitate 50% of VSG 221 or 121 were 100-fold to 1,000-fold higher than the effective concentration of homologous antiserum. VSG 116 (Fig. 1*d*) was even less effectively precipitated by the four heterologous antisera tested.

The extent of heterologous precipitation demonstrated in these experiments is more variable and considerably less than that experienced by Barbet and McGuire[8]. Several factors may combine to explain both this discrepancy and my own earlier failure, and possibly that of others, to detect significant crossreactions. In agreement with our previous experiences, Barbet and McGuire were unable to demonstrate crossreactions by gel immunodiffusion or by reaction of living trypanosomes with fluorescent antisera. These were the only techniques which I routinely used for screening the antigenic specificities of trypanosomes and purified VSGs. Only minimal use had been made of radioimmunoassay procedures and these had been performed using ^{35}S-formylmethionine sulphone-labelled[9] antigens having only 1% of the specific activity of the iodinated antigens used in the current experiments. Considering the low specific activity and small range of VSGs and antisera previously used, it is not surprising that we did not detect crossreactions. Recent experience suggests that the immunisation protocol used by Barbet and McGuire, particularly the use of very low amounts of VSG, is an additional factor in obtaining strongly crossreacting antisera.

Our findings[6,10] that native VSGs may be selectively cleaved by trypsin and the resultant large and small N-terminal and C-terminal fragments separated in the absence of denaturing agents, offered the possibility of determining whether the crossreacting determinants were localised in one region of the molecule. Large undenatured N-terminal tryptic fragments of molecular weights 52,000, 41,000 and 44,000 were purified from VSGs 55, 121 and 221 respectively. Antisera were raised against the fragments from VSGs 55 and 121. The three fragments were iodinated and their precipitation by heterologous and homologous antisera was investigated.

The results given in Fig. 1 *e*, *f*, *g* show that the tryptic fragments from VSGs 55 and 121 were efficiently precipitated by homologous antisera from rabbits immunised with either the corresponding fragment or the intact VSG. The fragment from VSG 221 was efficiently precipitated by antiserum against intact VSG 221. There was no precipitation of any N-terminal fragment by heterologous antisera, in striking contrast to the results obtained with the intact VSGs. A subsequent experiment with more strongly crossreacting antisera confirmed these results. Additionally, antisera raised against the N-terminal fragments of VSGs 55 and 121 were unable to precipitate intact VSG 221. All these results strongly suggest that the crossreacting determinants are not located in N-terminal fragments representing up to 80% of the intact molecule. However, crossreacting determinants might be formed by amino acid sequences in both N-terminal and C-terminal domains being brought into proximity by the overall conformation of the intact glycoprotein. In view of the ease with which the two domains dissociate on tryptic cleavage, this seems unlikely.

Confirmation that the C-terminal fragment was the unique location of crossreactivity, was sought by inhibition studies using a glycopeptide fraction representing the C-terminal 17,000 molecular weight initial cleavage product of VSG 121 (equivalent to VSG 52 in ref. 6). Carbohydrate is found only in the C-terminal 25% of VSG 121 (refs 6, 10). Following trypsin digestion of VSG 121, a glycopeptide fraction was purified by absorption on concanavalin A–Sepharose, followed by elution and rechromatography on Sephacryl–S200. A single peak of 14,000 apparent molecular weight was recovered from the Sephacryl column. At a 10-fold molar excess, this undenatured C-terminal glycopeptide fraction was able to inhibit by 80% the immunoprecipitation of intact VSG 55 by antiserum 121 (Table 1). A 540-fold molar excess of the N-terminal 52,000 molecular weight fragment of VSG 55 did not inhibit cross precipitation: neither did a 160-fold molar excess of the N-terminal 41,000 molecular weight fragment of VSG 121. These results suggest that the crossreactions can be attributed to the C-terminal regions of VSGs 55 and 121.

The second section of Table 1 shows the competitive effects of various amounts of unlabelled intact VSGs on the precipitation of radioactive VSG 55 by a dilution of antiserum 121 which gave 60% precipitation of VSG 55 in uninhibited controls. The effectiveness of different unlabelled competitor VSGs as inhibitors varied; VSGs 55, 121 and 60 were most effective, VSGs 221 and 116 were less effective and VSG 118 at a 1,000-fold excess was only partly competitive. The reason for these variations is not apparent. One implication is that the crossreacting determinants are not shared by all VSGs. In a region the size of the approximately 150 amino acid C-terminal domain, there might be several antigenic determinants which are shared to different extents by different groups of VSGs. On the other hand, the inhibition experiments of Barbet and McGuire[8] suggest a much greater uniformity of crossreactivity between all the VSGs tested by them. This discrepancy may reflect the relatively few VSGs now being studied in either laboratory. It is possible that immunological crossreactivity will identify the existence of different VSG subgroups. The use of monoclonal antibodies[11] might clarify the situation.

The C-terminal domain of VSG 121 contains all the carbohydrate; could carbohydrate be responsible for the immunological crossreactivity? This is not easy to confirm, but three relevant observations have been made. First, concanavalin A did not block the crossreactivity between VSG 55 and antiserum 121 (Table 1). Second, VSG 118, which was the least effective inhibitor of crossreactivity, contains more carbohydrate (17%

Unlabelled competitors were diluted in PBS containing 2 mg ml^{-1} bovine albumin. Assay conditions were otherwise as described for Fig. 1 except that the total incubation volume was 0.085 ml. 55 f52 and 121 f41 are the N-terminal tryptic fragments from VSGs 55 and 121. 121 f17 is a C-terminal fragment from VSG 121.

by weight) than any other VSG studied. Third, one experiment was performed in which the 121 C-terminal precipitation-blocking glycopeptide was treated with *Streptomyces griseus* endoglycosidase H (Miles). After treatment, the C-terminal fragment was repurified by passage through a column of concanavalin A–Sepharose, on which it was no longer retained. After removal of the oligosaccharide side chain, blocking activity was not eliminated but was reduced 10-fold. This reduction could be due to conformational changes arising during the several repurification steps which were used after glycosidase treatment. The possible role of carbohydrate in crossreactivity needs further investigation.

From the evidence of its susceptibility to proteolytic cleavage[6], the VSG C-terminal polypeptide region may be rather loosely folded. We must therefore also consider that slight denaturation may expose antigenic determinants in this area which are normally masked by the native configuration of the polypeptide.

It might reasonably be assumed that VSGs have evolved by gene duplication and mutation or are made by some kind of gene-splicing mechanism. Therefore, crossreactivity is perhaps not surprising. Another argument for some conservation of structure is that all VSGs must presumably attach to the plasma membrane in a similar manner. The crossreacting determinants are apparently masked on living trypanosomes[8] and so is the C-terminal region of the VSG[10]. These facts do not greatly encourage us to believe that crossreacting determinants could provide a basis for immunisation, although this possibility will undoubtedly be explored. The significance of crossreactivity must be clarified by immunochemical and amino acid sequence studies of a range of VSGs.

I thank A. F. Barbet for a preview of ref. 8, and Lyn Gurnett and Lynne Davey for technical assistance.

Dexamethasone-induced adhesion in hepatoma cells: the role of plasminogen activator

TRANSFORMED CELLS are frequently less adhesive than normal cells. This decrease in adhesion has been associated with the loss of specific cell surface proteins, changes in morphology, alterations in the underlying cytoskeleton and the increased activity of the serine protease, plasminogen activator[1–3]. Hepatoma tissue culture (HTC) cells exhibit increased levels of adhesion to glass[4,5] and decreased plasminogen activator activity[6,7] when incubated in the presence of the synthetic glucocorticoid, dexamethasone. Plasminogen activator converts plasminogen in serum to plasmin. It has been shown that plasmin causes the reversible dissociation of intracellular actin-containing cables in anchorage-dependent rat embryo cells[8] and may also be partially responsible for decreased adhesion of Rous sarcoma virus-transformed chicken embryo fibroblasts[3]. Cell–substrate adhesion presumably requires specific cell surface glycoproteins and intact cytoskeletal elements[9,10]. It is possible that plasmin acts either to modify 'adhesive' proteins on the cell surface or to disrupt linkages between these surface components and the underlying cytoskeleton. We have used variant HTC cells selectively resistant to the dexamethasone inhibition of plasminogen activator[6] to test the hypothesis that hormonal induction of cell adhesion is secondary to the inhibition of plasminogen activator which in turn allows the accumulation of the glycoproteins necessary for adhesion. We have modified cell adhesion assay techniques[5,11] to provide a sensitive measure of cell–substrate adhesion for both wild-type and variant HTC cells in the presence and absence of serum and plasminogen. We report here that plasminogen activator does not have an important role in the hormonal regulation of HTC cell adhesiveness.

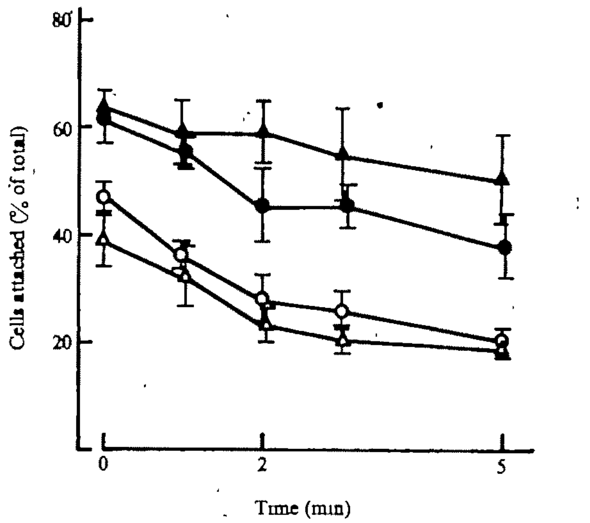

Fig. 1 Wild-type HTC cells were incubated overnight in radioactive medium containing 3% plasminogen-depleted fetal calf serum in the presence (●) or absence (○) of 0.1 μM dexamethasone, or in the same medium reconstituted with 4.8 μg ml^{-1} plasminogen in the presence (▲) or absence (△) of 0.1 μM dexamethasone. The assay conditions were the same as for cells incubated in serum-containing medium (see legend to Table 1). Plasminogen was obtained from outdated human plasma by affinity chromatography using lysine–Sepharose 4B (Pharmacia) followed by elution with ε-aminocaproic acid as described by Deutsch and Mertz[16]. Plasminogen-depleted serum was prepared by passing fetal calf serum through a lysine-Sepharose column and collecting the non-adsorbed fraction. This was acid treated to reduce the activity of protease inhibitors[17] and filter sterilised (0.45 μm pore size).

HTC cells were routinely grown in spinner culture without antibiotics in Eagle's minimal essential medium, modified to contain 2 mM glutamine, 5% each heat-inactivated fetal calf and calf serum (Grand Island Biological), 5.8 mM $NaHCO_3$ and 50 mM Tricine (Sigma). Variant HTC cell lines fully resistant to the dexamethasone inhibition of plasminogen activator were isolated using an agar–fibrin overlay technique to detect plasminogen-activator production by individual colonies of cells[6]. Glucocorticoid-receptor function was determined to be normal in variant cell lines on the basis of normal tyrosine aminotransferase induction by dexamethasone, assayed as described by Spencer and Gelehrter[12].

Wild-type HTC cells incubated for 18 h in serum-containing medium in the presence of 0.1 μM dexamethasone typically show a twofold increase in the per cent of cells remaining attached to a glass surface after 5 min of shaking, when compared to untreated cells (Table 1). After cells have been allowed to settle and attach, differences in adhesion between dexamethasone-treated and untreated cells are evident. In the presence of dexamethasone there are fewer loosely adherent cells initially, and those which remain after settling are more adherent than those in the untreated cell population. In the conditions of the assay, maximal detachment occurs within 2–5 min. We find that dexamethasone also induces adhesion in variant HTC cells which are resistant to the dexamethasone

0028-0836/79/0277—0312$01.00

inhibition of plasminogen activator (Table 1). Although variant C cells are less adhesive than the wild-type HTC cells, there is a twofold increase in the adhesion of dexamethasone-treated cells incubated in the presence of serum. Two other HTC cell variants, A and B, which are also fully resistant to the dexamethasone inhibition of plasminogen activator, have similar dexamethasone-induced adhesion (data not shown). These results suggest that the mechanism by which dexamethasone increases cell-substrate adhesion does not depend on the inhibition of plasminogen activator.

When incubated in serum-free medium, wild-type HTC cells again show a twofold increase in adhesion in the presence of dexamethasone (Table 1). Variant C cells are less adhesive than the wild-type HTC cells in these conditions as well, but also show a twofold increase in adhesion when incubated in the presence of dexamethasone (Table 1). Likewise, variants A and B consistently exhibit dexamethasone-induced adhesion in the absence of serum. In both wild-type and variant HTC cells, the induction of adhesion by dexamethasone occurs to a similar extent in the presence and absence of serum.

We have also directly tested the effects of plasminogen, the substrate for plasminogen activator, on the dexamethasone induction of adhesion in wild-type and variant HTC cells in serum-free conditions. If the formation of plasmin from plasminogen prevents the accumulation of cell surface proteins required for adhesion, then the addition of plasminogen to serum-free medium should decrease or prevent dexamethasone induction of adhesion in the variant cell lines. Instead, we find that dexamethasone induces increased levels of adhesion in both wild-type and variant cells which have been incubated for 18 h in medium containing plasminogen (data not shown). This also suggests that plasminogen-activator activity does not modulate the adhesive response to dexamethasone.

Wild-type or variant HTC cells were collected from spinner culture during the logarithmic stage of growth. Cells were resuspended in medium containing 3% fetal calf serum, 0.1 μCi ml^{-1}, ^{3}H-amino acid mixture (NEN) and 50 μg ml^{-1} neomycin, in the presence or absence of 0.1 μM dexamethasone (Merck). After an 18-h incubation at 37 °C in a gyrotory shaker-waterbath at 80 r.p.m., the cells were centrifuged, and the cell pellet washed twice in nonradioactive medium and resuspended to a final density of 10^6 cells ml^{-1} in nonradioactive medium. Cell viability, as measured by trypan blue exclusion, was always greater than 90%. One-ml aliquots of the cell suspension were distributed into untreated borosilicate glass scintillation vials and incubated without shaking for 2 h at 37 °C. At the end of the incubation period, the cells completely covered the surface of the vial with little or no piling up of cells. The medium was removed and 1 ml calcium- and magnesium-free phosphate-buffered saline (PBS), *p*H 7.3, added carefully down the side of each vial. The vials were then subjected to a shearing force of 100 strokes mm^{-1} in a Dubnoff reciprocating shaker-waterbath (5-cm stroke) at 37 °C. At 0, 2 and 5-min exposure to this reciprocating force, duplicate vials were removed and the PBS aspirated. Cells adhering to the glass scintillation vials were lysed with 0.1 ml 1 M KOH and the lysate neutralised with 0.1 ml 1 M HCl. Radioactivity was assayed in a scintillation spectrometer after addition of 5 ml ACS scintillation fluid (Amersham–Searle). In control experiments not shown, cells were removed from the surface of vials by trypsin following the 5-min shaking period. These cells were viable by the criterion of trypan blue exclusion and the cell counts correlated with direct measurements of radioactivity in each vial. Radioactivity of the initial cell inoculum was determined from 1-ml aliquots of the cell suspension which were centrifuged, the cell pellets lysed in 0.1 ml 1 M KOH and the lysate neutralised in 0.1 ml 1 M HCl. The per cent of initial labelled cell inoculum remaining after shaking (average of duplicate vials) has been used as a measure of cell adhesiveness. The data presented represent the mean ± s.e.m. calculated from several experiments. In experiments carried out in serum-free medium (supplemented with 0.1% BSA), the assay was modified to include a 1-h incubation period for cell attachment and a reciprocating force of 140 strokes mm^{-1}.

In conditions in which plasminogen is the only serum factor missing, wild-type cells exhibit a twofold increase in adhesion in the presence of dexamethasone (Fig. 1). When cells are incubated for 18 h in medium containing depleted serum which has been reconstituted with plasminogen, a similar, although somewhat greater, increase in adhesion is measured in dexamethasone-treated cells. In the absence of dexamethasone, cell adhesion is the same whether the medium contains plasminogen-depleted or reconstituted serum. These results also suggest that plasminogen-activator production does not have a major role in cell–substrate adhesion.

Note that the optimal assay conditions differ in the presence and absence of serum. When serum is present, cell–substrate adhesion may depend on interactions between the cell surface and serum proteins which are adsorbed to the glass[13]. This might be relevant to our observation that HTC cells incubated in serum-containing medium require a longer time to form stable adhesive bonds to a substrate than do cells in serum-free medium containing bovine serum albumin (BSA). It has been proposed that cell surface proteases on BHK cells modify substrate-adsorbed proteins during the process of cell adhesion[14]. Although other cell surface proteases may be involved in cell–substrate adhesion, the nearly identical adhesiveness of untreated HTC cells in fetal calf serum, plasminogen-depleted serum and reconstituted serum provides additional evidence which tends to rule out any important role for plasminogen activator or plasmin in this process.

Recently, a class of dexamethasone-induced proteins, tentatively described as sialogylcoprotein on the basis of electrophoretic properties in a two-dimensional gel system, has been localised on the surface of HTC cells[15]. It is possible that such proteins could confer increased adhesive properties on hormone-treated cells. Our data suggest that dexamethasone regulation of cell adhesion in HTC cells probably operates primarily through the synthesis of surface glycoproteins and that this process is not, in turn, regulated by the inhibition of plasminogen-activator activity.

We acknowledge the preliminary studies on HTC cell adhesion carried out in this laboratory by Ms Lana Seguin. This work was supported by NIH grants GM 15419 and CA 22729. Glucocorticoids regulate the concentration of 1,25-dihydroxycholecalciferol receptors in bone

THE results of a study of high-affinity glucocorticoid and 1,25-dihydroxycholecalciferol ($1,25(OH)_2D_3$) binding in cytosol from fetal rat calvaria cultured for up to 48 h at 37 °C are presented. The binding of glucocorticoids was found to be stable in short-term culture, whereas that for $1,25(OH)_2D_3$ declined rapidly, was almost undetectable at 24 h and had disappeared by 48 h. Furthermore, low concentrations of cortisol (10^{-8} to 10^{-6} M) added to the culture medium had a dramatic effect on the persistence of high affinity $1,25(OH)_2D_3$ binding. In the presence of cortisol there was dose-dependent preservation of most of the binding of $1,25(OH)_2D_3$ in the cytosol. $1,25(OH)_2D_3$ is a potent agent in inducing bone resorption *in vitro* and these data suggest that glucocorticoids may exert part of their effects on calcium metabolism and bone *in vivo* by directly regulating the turnover of cytosol $1,25(OH)_2D_3$ receptors in one or more types of bone cell.

We recently developed a simple method for the detection of high-affinity glucocorticoid binding ($K_D \simeq 5\times10^{-9}$ mol l^{-1}) in fetal rat calvaria cytosol[1] and, by applying a similar method we also detected binding of similar affinity ($K_D \simeq 2.3\times10^{-9}$ mol l^{-1}) for $1,25(OH)_2D_3$ (ref. 2). Glucocorticoid receptors had been previously demonstrated in bone cells by Feldman *et al.*[3], and $1,25(OH)_2D_3$ receptors in bone calvaria cytosol in a preliminary report by Kream *et al.*[4]. In the latter study bone cytosol receptors for $1,25(OH)_2D_3$ were shown by sucrose density gradient centrifugation to have sedimentation characteristics (3.5S) similar to the better-defined $1,25(OH)_2D_3$ receptors of intestine. We have confirmed this finding (data not shown). In our method, in contrast to others, the equilibrium was set up first in the intact calvaria at 4 °C and then the cytosol prepared by sonication and ultracentrifugation, and bound separated from free steroid with dextran-charcoal. The advantages of this method are its simplicity, elimination of the risk of degradation of receptors and loss of cells during collagenase digestion, and the establishment of binding to intracellular receptors at their physiological concentrations.

The bound:free ratio in the cytosol using tracer-labelled glucocorticoid or $1,25(OH)_2D_3$ (10^{-9} mol l^{-1}) is as high as 60% displacing down to 5–10% with 100-fold excess of unlabelled steroid. Cross-competition experiments with up to 1,000-fold excess competing steroid showed that the glucocorticoid and $1,25(OH)_2D_3$ receptors are quite distinct from one another.

Although only a rough assessment of K_D or binding-site concentration is possible by this method, it is highly reproducible both for glucocorticoids and $1,25(OH)_2D_3$, and we have found the binding characteristics to be similar to those obtained in cytosol prepared by the methods of Feldman *et al.*[3] for glucocorticoids and Kream *et al.*[4] for $1,25(OH)_2D_3$ respectively. The reproducibility is due in part to the very slow rate of dissociation of glucocorticoids and $1,25(OH)_2D_3$ from their respective receptors as a consequence of dilution after cell disruption, which seems not to be significant over the 1–4 h elapsing between sonication of calvaria and the final charcoal separation step. This simple method is suitable for semi-quantitative study of changes in overall receptor content during culture of intact bone.

A marked difference was observed between the stability in short-term organ culture of the rat calvaria cytosol receptors for glucocorticoids, and $1,25(OH)_2D_3$ (Fig. 1). High-affinity glucocorticoid binding persisted for 24 h unchanged, while that for $1,25(OH)_2D_3$ diminished progressively after 2 h in culture and was minimal by 24 h. This marked difference suggested to us that $1,25(OH)_2D_3$ cytosol receptor content is being actively maintained by some agent or agents *in vivo* that are missing from the culture medium.

Oestradiol or testosterone (each at 10^{-6} M) had no effect on the rate of disappearance of $1,25(OH)_2D_3$ binding. These steroids lack specific cytosol receptors[3,5] in rat calvaria. However, a marked and dose-dependent effect of the glucocorticoid cortisol was demonstrated over the range 10^{-8} to 10^{-6} M (Fig. 2). There was no consistent effect at 2 h, but a dramatic preservation of $1,25(OH)_2D_3$ binding at 6, 24 and 48 h. After culture for 48 h in the absence of cortisol there was no residual high-affinity $1,25(OH)_2D_3$ binding, while in the presence of cortisol (10^{-6} M) binding was preserved at the level seen after 24 h of culture with cortisol. When calvaria were cultured for the first 24 h without steroid, and cortisol (10^{-6} M) subsequently added and culture continued for a second 24 h, binding of $1,25(OH)_2D_3$ was not restored but showed no further fall over the second 24 h.

When other glucocorticoids were tested in this system at 10^{-7} M for 24 h, they all significantly preserved binding of $1,25(OH)_2D_3$. Their relative efficacies in preserving $1,25(OH)_2D_3$ were closely related to their relative potencies as glucocorticoids and affinities for the glucocorticoid receptors (triamcinolone acetonide > dexamethasone > cortisol > corticosterone > progesterone).

These findings strongly suggest that glucocorticoids are important for maintaining the content of cytosol receptors for $1,25(OH)_2D_3$ in bone, and favour an inhibition of degradation of existing $1,25(OH)_2D_3$ receptors, rather than the induction of synthesis of new receptors. Our present data do not define the mechanism, but suggest that it is mediated by binding of the glucocorticoid to its receptor. It is of potential physiological importance since it occurs at physiological concentrations of glucocorticoids.

The effects of glucocorticoids on bone are of clinical significance, being involved in the rapid and severe bone loss seen in Cushing's syndrome and in patients on steroid therapy. In the presence of excess glucocorticoids, intestinal calcium

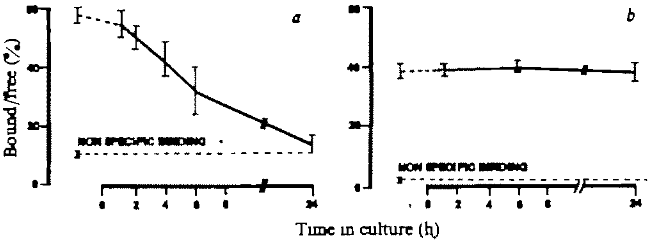

Fig. 1 Comparison of persistence of fetal rat calvaria glucocorticoid (*b*) and $1,25(OH)_2D_3$ receptors (*a*) in short-term organ culture at 37 °C. Cells were cultured on stainless steel grids, two half calvaria per grid, in sterile plastic Petri dishes with 0.3 ml culture medium under and in contact with each grid, in an atmosphere of 5% CO_2 in air at 37 °C. Culture medium was medium 199 (Flow Labs) with 1.2% $NaHCO_3$, 40 μg ml^{-1} gentamicin, 1 mM glutamine, 0.15 mg ml^{-1} ascorbic acid and 5% heat-inactivated rabbit serum (fluorometry revealed up to 1.45×10^{-8} M corticosterone in medium). All calvaria were kept at 4 °C except during the period of culture (0, 1, 2, 4, 6 or 24 h). After culture they were washed and again left in fresh culture medium at 4 °C. On completing this for the last set of calvaria, they were washed this time in incubation medium and incubated overnight in lots of four half-calvaria at 4 °C in 0.5 ml of this solution containing 1×10^{-9} M ^3H-labelled, with or without 100-fold excess unlabelled steroid. For detecting the glucocorticoid receptor $1,2,4(N)[^3H]$triamcinolone acetonide (Radiochemical Centre, Amersham, TRK 485, specific activity 29 Ci $mmol^{-1}$) was used as ligand because of its high affinity, and for the $1,25(OH)_2D_3$ receptor $23,24(N)$ $[^3H]1,25(OH)_2D_3$ (94 Ci mmol Amersham TRK 588) was used in place of the lower specific activity compound used in our earlier studies[2]. After overnight incubation, calvaria were washed again, sonicated, and the sonicate ultracentrifuged (100,000*g* for 30 min) bound and free separated with charcoal, and bound and total radioactivity counted[1,2]. Mean and range of observations of bound·free ratio from three separate experiments are indicated (six observations, each the mean of duplicates per time-point, for both steroids). The first data points are for controls at 4 °C.

0028-0836/79/0277—0314$01.00

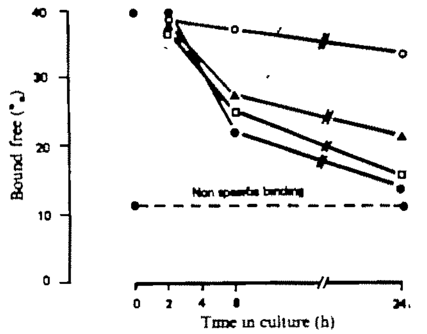

Fig. 2 Representative experiment showing the effect of including cortisol in the incubation medium on the persistence of $1,25(OH)_2D_3$ receptors in fetal rat calvaria. Each point is the mean of duplicate observations in cytosol from four half-calvaria. Incubations with 100-fold excess $1,25(OH)_2D_3$ indicate nonspecific binding which remained unchanged. In the absence of added cortisol (●) there was progressive loss of high affinity binding to very low levels at 24 h. ○, ▼ and □ indicate results in the presence of 10^{-6} M, 10^{-7} M and 10^{-8} M cortisol respectively.

absorption[6] and bone formation are reduced and bone resorption increased[7]. Numerous studies both *in vivo* and *in vitro*, in animals and man however have not fully elucidated the mechanism of these effects[8–12], although recent studies indicate that one action of glucocorticoids in birds[13] and possibly in mammals[14] is to stimulate renal 1α-hydroxylase activity. Our data indicate for the first time that glucocorticoids may influence the stability of cytosol $1,25(OH)_2D_3$ receptors in bone. From these experiments we cannot tell if this effect is specific to one population of bone cells or a general one affecting both osteoblasts and osteoclasts. There is evidence that both types of cell respond to $1,25(OH)_2D_3$ at concentrations of 10^{-9} M (ref. 15). An augmentation of $1,25(OH)_2D_3$ receptors in osteoclasts which would result from retarding their degradation might enhance bone resorption, since this metabolite of vitamin D is among the most potent bone-resorbing agents known[16,17].

Our studies indicate the need for a thorough examination of the effects of glucocorticoids on $1,25(OH)_2D_3$ and other receptors in cytosol and nuclei in isolated bone cell populations and in intestinal cells.

We thank the North West Regional Health Authority and the MRC for their support, Mrs C. M. Case for technical assistance and Dr C. M. Taylor and Professor S. W. Stanbury for help and advice.

Is the benzodiazepine receptor coupled to a chloride anion channel?

HIGH affinity saturable binding sites for benzodiazepines (BZs) in mammalian brain have been described[1]. These sites show stereospecificity, organ and subcellular distribution, and structure–activity relationships reminiscent of other synaptic membrane receptors which have been characterised by ligand binding[2,3]. The BZ receptor is so highly selective that no known putative neurotransmitters interact with it, thus raising the possibility that the brain contains another unidentified endogenous ligand[4,5]. Recently, Tallman *et al.* have reported that γ-aminobutyric acid (GABA) specifically enhances the binding of ^{3}H-diazepam to rat brain membranes[6]. Considerable biochemical and neurophysiological evidence suggests that GABA may be intimately involved in the mechanism of action of BZs[7–10,18]. In several neurotransmitter systems, ions seem to have specific effects on the binding of synaptic receptor ligands, presumably because of the intimate association of the receptor with an ion channel. For example, binding of opiate agonists and antagonists is differentially affected by sodium ion[11], and Na^+ conductance is altered by opiate agonists[12]. Similarly, specific effects of anions on the receptors for strychnine[13] and GABA[14] are correlated with observations that the neurophysiological action of these receptors is dependent on alterations in chloride ion conductance[15,16]. We now report the specific effect of chloride and other anions in enhancing BZ binding to its receptor. We infer that the BZ receptor (recognition site) may be

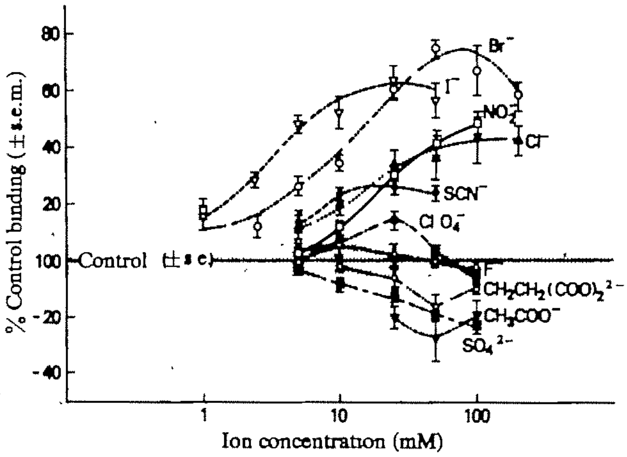

Fig. 1 Effect of various anions on ^{3}H-diazepam binding. Male rats (200–250 g) were decapitated. Cerebral cortices were washed quickly in ice-cold Tris-maleate buffer (50 mM, *p*H 7.6 at 0 °C), homogenised in 100 vol of the same buffer (w/v) using a Brinkmann Polytron for 20 s and centrifuged at 20,000 *g* for 20 min at 7 °C (J-21 Beckman centrifuge). Pellets were resuspended by Polytron in 100 vol of buffer. Radioreceptor assay incubations contained 0.5 ml of membranes, 0.3 nM ^{3}H-diazepam (~80 Ci mmol^{-1}, NEN), 0.1 ml of the added salt solution (or distilled water as control) and buffer in a total volume of 1 ml. After incubation for 30–45 min at 0 °C, tubes were rapidly filtered through glass fibre filters (GF/B, Whatman) *in vacuo*. Filters were washed twice with 5 ml of cold buffer, dried, extracted with 10 ml Aquasol (23 °C for 10 min with vigorous shaking) and counted in a Beckman scintillation counter with 40% efficiency. The *p*H of the incubation medium was unperturbed by any of the ionic additions. Anions were all added as ammonium salts, except for succinate and nitrite which were sodium salts. Nonspecific binding measured in the presence of 1 μM unlabelled diazepam was unaffected by the ions, even at the highest concentrations, and was 7.5±2% of the maximal binding. Each point indicates the mean of three determinations. Triplicate control tubes were placed at the beginning and end of each dose–response curve to detect any instability. For clarity, data for representative inactive anions have been plotted (compare with Table 1). All inactive anions produced either no significant effect on ^{3}H-diazepam binding or, more often, a small (<20%) inhibition of binding.

Table 1 Effects of anions on ^{3}H-diazepam binding: correlation with effects on permeability

Anion	Enhancement of binding	Permeability (Eccles[15])	ED_{50} (mM)	E_{max}* (% control binding)
Iodide	+	+	2.8	160
Bromide	+	+	9.0	175–180
Chloride	+	+	13.0	142
Nitrite	+	+	20.0	148
Thiocyanate	+	+		126
Perchlorate	+/−	+		
Chlorate	−	+		
Azide	−	+		
Formate	−	+		
Fluoride	−	−		
Oxalate	−	−		
Succinate	−	−		
Acetate	−	−		
Sulphate	−	−		
Lactate	−	−		
Propionate	−	−		
Maleate	−	−		
Phosphate	−	−		

There were no significant effects of choice of anion, for example, Na^+, K^+, NH_4^+, in the case of bromide or iodide.

* E_{max}, maximal binding relative to control.

closely associated with a chloride ion channel which is also closely linked to the GABA-recognition site.

A crude membrane preparation from rat brain, obtained and incubated in an organic buffer (Tris-maleate), was assayed for ^{3}H-diazepam binding in the presence of increasing concentrations of some anions; a dose-dependent enhancement of specific binding was demonstrated (Fig. 1). Of 18 anions tested, only five proved to be clearly active—iodide, bromide, chloride, thiocyanate and nitrite. Inactive anions included organic, monovalent (formate, acetate, lactate, propionate) and divalent (oxalate, succinate, maleate), as well as inorganic, monovalent (fluoride, azide, chlorate) and divalent (sulphate). Perchlorate was active only at 25 mM. Since the dose–response curve for each of these anions differs both in regard to ED_{50} and maximal effect, it is difficult to assess a single sequence of potency. In terms of ED_{50}, iodide is the most active (2.8 mM). The maximal effect was observed with 50 mM bromide, which increases the specific binding 70% over the control. For these two anions, significant enhancement of binding was observed with concentrations as low as 1 mM. Further increase in concentration of active ions resulted in a decrease of the binding, perhaps due to nonspecific effects, consistent with the observation that most of the inactive anions tested were also slightly inhibitory at higher concentrations. The observations were independent of the cation—sodium, potassium and ammonium salts of bromide showed no statistically significant differences in their effectiveness. The effect of anions was to alter specific binding; there were no changes in nonspecific binding values for any anion tested, even at massive concentrations.

The magnitude of the anion effect is strongly dependent on temperature, being maximal at 0 °C and completely abolished at 37 °C. To characterise the anion-dependent increase of binding further, dose–response curves of the inhibition of ^{3}H-diazepam binding by increasing concentrations of unlabelled ligand in the presence or absence of iodide (25 mM) were obtained, and these data used to construct a Scatchard plot (Fig. 2). The enhanced binding was due to an increase in the affinity constant, while the number of binding sites was unchanged. Pooling data from three experiments, we obtained a mean K_d value of 3.57 ($\pm$0.3 s.e.m.)$\times 10^{-9}$ M in the absence of ion, which decreased to 2.4 ($\pm$0.13)$\times 10^{-9}$ M in the presence of 25 mM iodide. The mean binding capacity was 54 ($\pm$9.7) fmol mg^{-1} (original weight) for the control and 60 ($\pm$10.5) fmol mg^{-1} with added iodide. This latter difference was not statistically significant. The change in the apparent equilibrium constant is attributable to a change in the dissociation rate constant without alterations in the association rate constant: the $t_{1/2}$ for dissociation is 3.5 min ($\pm$0.52) for the control and 6.2 ($\pm$0.91) in the presence of 25 mM iodide (Fig. 2, inset). Association curves with or without ionic additions showed no appreciable difference in the association rate constant, but only in the plateau value due to the change in K.

The selectivity of the effective anions on binding is in excellent agreement with their selectivity for penetrating the activated inhibitory postsynaptic membrane of cat motoneurones measured electrophysiologically[17] (Table 1). Every anion which increased diazepam binding has been reported to convert the inhibitory postsynaptic potential into the depolarising direction. Of particular note is the complete inactivity of fluoride, both in the binding assay and the electrophysiological studies, in spite of the high potency of the other halides. Chlorate, azide and formate, however, failed to enhance ^{3}H-diazepam binding, but seem to pass through the chloride channel[15]. A weak anion effect might easily be masked by the nonspecific inhibitory effect (due to increased ionic strength) that we observed with all the anions tested (at high concentrations for the active ion and at lower concentrations for the inactive ions). For example, perchlorate showed an enhancement of binding at only one concentration (25 mM). Alternative explanations for the anion effect which invoke nonspecific effects (ionic strength, chaotropic effect or effects on water structure in the vicinity of the membrane) are relatively unlikely. Chlorate, for instance, is a strong chaotropic agent[19] but is inactive in this system.

The failure to find enhancement of ^{3}H-diazepam binding by anions has been reported[20], but those authors used Tris-HCl buffer, which obscures the effect.

The temperature dependence of the effect[29] which is reminiscent of the sodium effect on opiate binding[21], the change

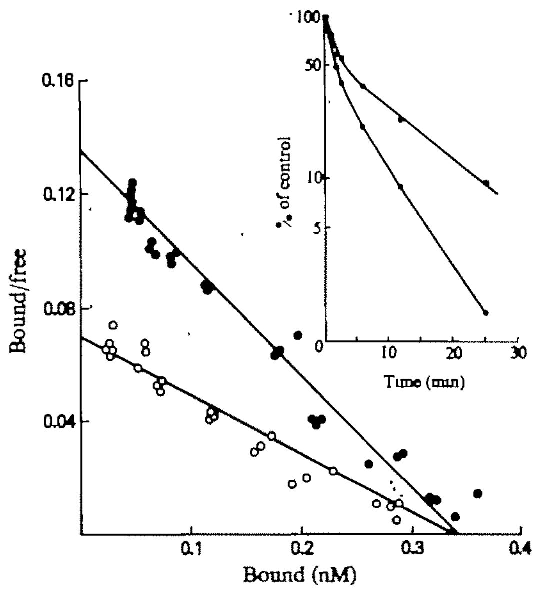

Fig. 2 Scatchard analysis of ^{3}H-diazepam binding in the presence (●) or absence (○) of 25 mM NH_4I. Assay conditions as described for Fig. 1 with a fixed amount of ^{3}H-diazepam (0.15 nM) and varying concentrations of unlabelled ligand. Data from three experiments were analysed with a weighted, nonlinear, least squares, curve-fitting program (SCATFIT)[27,28]. Binding parameters were compared within experiments using a paired analysis. In all three experiments, a major change in affinity was detected, whereas the binding capacity was not significantly affected. The equilibrium constant of association (K) was increased by a factor of 1 39 ($\pm$0.04) ($P<0.01$), and the ratio of binding capacities was 1.12 ($\pm$0.09). Inset shows the dissociation curves in the presence (○) and absence (●) of 25 mM NH_4I. The ratio of the corresponding $t_{1/2}$ values (1 77) is sufficient to explain the difference in the equilibrium constants without a change in the association rate constant.

in affinity due to a change in the dissociation rate constant, and the apparent specificity of the anions involved, all suggest that ions modulate the affinity of the BZ receptor through an allosteric-induced change of conformation. Recent experiments in our laboratory[29] have demonstrated that the GABA-induced increase in diazepam binding can be increased markedly and synergistically by including halides in the incubation medium. Since neurophysiological[22-24] and binding studies[25] already indicate an association of GABA receptor to chloride ion channels, the present data further support the concept that GABA and diazepam receptors are closely associated and may be jointly coupled to a chloride ion conductance mechanism, at least in some regions of the brain.

An interesting speculation about the nature of the endogenous ligand for the diazepam receptor may be made on the basis of analogy with the effects of ions on the opiate, GABA, and α-adrenergic receptors[26]. In these three systems, antagonist binding is unaffected or enhanced by the ion related to the conductance mechanism, whereas agonist binding is inhibited by the same ion. If this were to represent a general phenomenon, it could be predicted that the endogenous ligand for the 'Valium' receptor would be an 'agonist', while BZs themselves are antagonist compounds; in other words, the endogenous ligand should be an 'anxiety factor'.

Transplacental effects of chemical mutagens detected by the micronucleus test

EXPOSURE to chromosome-damaging chemicals during prenatal development is particularly hazardous, since stem-cells needed to support tissue maintenance throughout life may then be at risk. Lesions in fetal cells lead to cancer in early life, and in germ-cell lineages, contribute to increased inherited abnormalities. Chemicals can be screened for chromosome-breaking potential *in vivo* by the micronucleus test[1] which measures frequencies of acentric chromosome fragments[2]. Micronuclei are usually scored in polychromatic erythrocytes from adult rodent bone-marrow. This short-term test is claimed to be as reliable as the more laborious analysis of metaphase chromosomes for chemically-induced visible aberrations[3,4]. The reactive forms of chromosome-damaging chemicals are often metabolites formed within tissues of exposed individuals. Short-term methods to determine genome-damaging potential must incorporate realistic activating systems if derived risk-estimates are to be meaningful. Although fetal organs contain enzymes which activate mutagenic/carcinogenic chemicals[5], the micronucleus test has not previously been applied to transplacental exposure. Adult bone marrow has limited activation capacity and short lived mutagens/carcinogens formed in other tissues may not survive in the circulation, so false-negative results can be obtained. Late in gestation, blood cells develop in the fetal liver, alongside hepatocytes which metabolise pre-mutagens/carcinogens to active forms. We show here that transplacental exposure to chemicals which require metabolic activation can cause chromosome breakage, indicated by micronucleus formation, in mouse fetal tissue. The dose dependence of this intrauterine genetic damage can be measured, thus providing a method for quantitative assessment of risks inherent in prenatal exposure to certain classes of carcinogenic and mutagenic chemicals.

The kinetic model presented in Fig. 1 (data from refs 6–9) predicts that transplacental and maternal effects of chromosome-damaging agents could be compared by measuring the incidence of polychromatic erythrocytes containing micronuclei in fetal liver 12–18 h after the effective exposure to the test agent, and in both maternal bone marrow and fetal blood 30 h after the effective exposure. The essential parameters on which this prediction is based are as follows. Optimal expression of chromatid and chromosomal damage occurs if the toxic agent

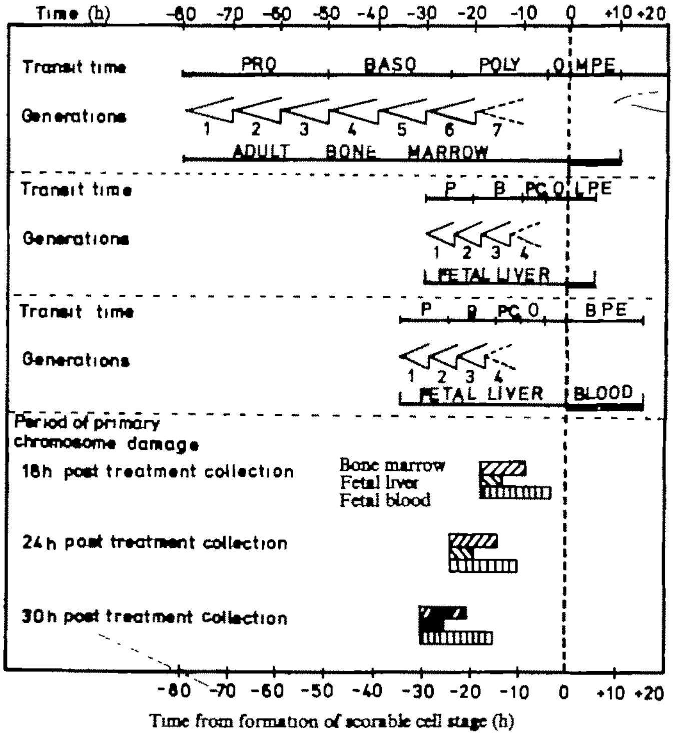

Fig. 1 Kinetic basis for optimal 'expression time' of chromosome lesions giving rise to micronuclei in polychromatic erythrocytes of maternal bone marrow, and fetal liver and peripheral blood, after treatment with chemical mutagens/carcinogens (Pro (P), proerythroblast; Baso (B), basophilic; Poly (PC), polychromatic; O, orthochromatic erythroblasts; MPE, LPE and BPE bone marrow, fetal liver and fetal blood polychromatic erythrocytes, respectively). The dotted line indicating the cell generation within the polychromatic erythroblast class is to show that some of these cells will be post-mitotic.

0028-0836/79/0277—0317$01.00

reaches effective concentrations during the penultimate cell division cycle of erythroblast maturation. Adult bone-marrow erythroblasts undergo six to seven divisions, the last two occupying about 20 h. The post-mitotic cells develop for 10 h until nuclear extrusion is completed and the resulting polychromatic erythrocyte remains in the bone marrow for about 10 h. Fetal liver erythroblasts (after the 16th day of gestation) undergo four divisions, the last two occupying about 12 h. The post-mitotic cells develop for about 5 h until nuclear extrusion is completed, and the polychromatic erythrocyte remains in the fetal liver for about 5 h. Once in the fetal circulation it persists in its early form, with homogeneously distributed cytoplasmic RNA, which gives characteristic staining properties, for about 15 h.

If each target cell received damage leading to formation of a single micronucleus, the maximum incidence of polychromatic erythrocytes containing micronuclei in fetal liver and bone marrow would be ~25%. However, this maximum may not be expressed, as doses causing this degree of damage would be likely to cause other cellular lesions, and interfere with erythroid maturation.

As the daily output of early erythrocytes from the liver is about 60% of the number already in the fetal circulation, the frequency of micronucleated early polychromatic erythrocytes in the blood will be about 60% of the peak in the fetal liver.

These predictions were tested by exposing 15–16-d pregnant Swiss-albino mice to 2 mg per kg mitomycin-C. This substance, produced by the soil microorganism *Streptomyces caespitosus*, is biologically inactive in its natural state but is converted to mono- and bifunctional alkylating agents *in vivo* after reduction to hydroquinone derivatives by NADPH-dependent quinone reductase. The chromosome-damaging potential of mitomycin-C has been established in a variety of plant and animal systems and the agent has been used in the treatment of advanced cancers. The data in Fig. 2 indicate that the predictions of our model are substantially fulfilled. The dose of 2 mg per kg intraperitoneally (i.p.) (~40% of the intravenous LD_{50}) induces approximately twice the frequency of micronucleated erythrocytes in the adult bone marrow as in the fetal liver. The spontaneous incidence of micronucleated erythrocytes was 0.16±0.03% in adult bone marrow, 0.40±0.08% in the fetal liver, and 0.24±0.09% in the fetal blood.

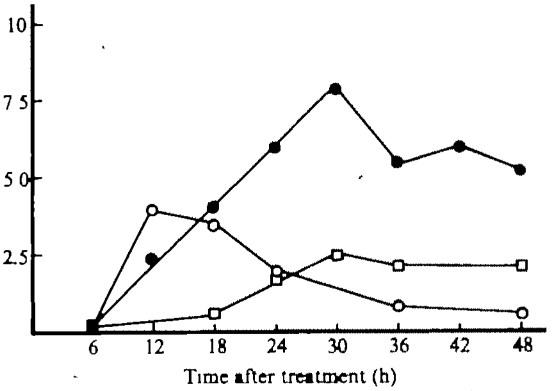

Fig. 2 Time course of incidence of polychromatic erythrocytes (PCEs) containing micronuclei in maternal bone marrow (●), fetal liver (○) and fetal blood (□) after a single i.p. administration of 2 mg per kg mitomycin-C. Data from two experiments. Total of at least four pregnant animals and two fetuses per litter examined for each point. Single cell suspensions of fetal liver and adult femoral bone marrow were prepared in freshly filtered (0.22 μm pore size) Hank's balanced salt solution +5% fetal calf serum, by repeated pipetting. Slides were prepared on a 'Cytospin' (Shandon) (4×10^4 nucleated cells in 0.2 ml per slide). Blood films were prepared directly from dissected fetuses. Slides were air dried, fixed in absolute methanol, and stained: May Grunwald (Merck) 0 25% in methanol 3 min, May Grunwald as above diluted 1:1 with Sorenson buffer, pH 6.8, 2 min; Giemsa (Merck) 14% v/v in Sorenson buffer, pH 6.7, 10 min. Stained slides were rinsed briefly in buffer followed by distilled water (total 30 s for bone marrow, 45 s for fetal liver and blood). All solutions were filtered through Whatman GFC immediately before use. This protocol maximises the distinction between polychromatic erythrocytes (blue cytoplasm) and mature erythrocytes (yellow-orange cytoplasm) and stains micronuclei red-purple. Air-dried slides were mounted in DePex. A minimum of 1,000 polychromatic erythrocytes were evaluated per slide with a 100× objective.

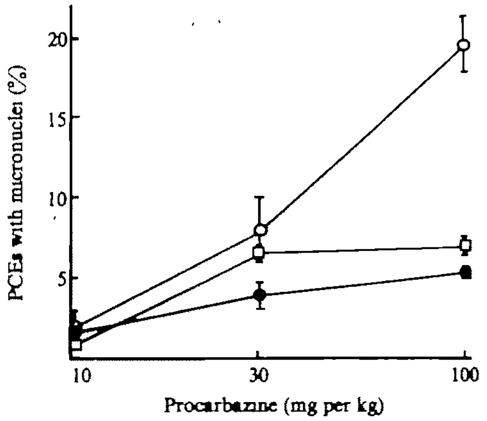

Fig. 3 Dose responses to procarbazine. Fetal liver (○), fetal blood (□) and maternal bone marrow (●) were examined for frequency of polychromatic erythrocytes (PCEs) containing micronuclei 12, 18, 24, 30 and 36 h after 10, 30 or 100 mg per kg procarbazine had been administered by single i.p. injection. At least three pregnant animals and two fetuses from each of the three litters were examined per point. Data plotted from time giving maximum incidence for each dose and tissue and expressed as mean ± s.e.

Similar tests were carried out with procarbazine hydrochloride, another anti-neoplastic drug, using single i.p. injections of 100 mg per kg (40% of LD_{50}), 30 mg per kg and 10 mg per kg. This agent is enzymatically converted to biologically active formaldehyde, methyldiazene and methyl radicals, through azo procarbazine. Activity of the three available routes (N^1 hydroxylation, N^1 demethylation or N^2 hydroxylation) may vary between tissues. Although clearly mutagenic to mammalian cells *in vivo*, mutagenicity of procarbazine cannot be reliably detected by *Salmonella* or *Saccharomyces* systems[10–12]. Figure 3 shows that dose–response curves can be constructed from all three tissues examined. Fetal liver is more damaged by procarbazine than adult bone marrow.

These preliminary experiments establish the usefulness of the erythrocyte micronucleus test applied to prenatal mice. The frequency of spontaneous micronucleus formation in the fetal liver is low, and preparations of fetal liver and fetal blood cells for microscopic observation are simply made and scored. We are extending this analysis to a wider range of environmentally significant mutagens and carcinogens, including those which have given negative results in the standard adult erythrocyte micronucleus test.

Reduction of benzo(*a*)pyrene mutagenicity by dihydrodiol dehydrogenase

THE enigma of how inert chemicals can exert potent mutagenic, carcinogenic, allergenic and cytotoxic effects has been much debated. It has been learned that such compounds are metabolically converted to chemically reactive species[1]. In the case of aromatic or olefinic compounds, monooxygenases located in the membranes of the cell can transform these compounds into epoxides[2–5] which by virtue of electrophilic reactivity can bind chemically to cellular macromolecules such as DNA, RNA and proteins, thereby disturbing biochemical control mechanisms and leading to the above mentioned toxic effects. The same membranes in which such epoxides are produced possess an enzyme, epoxide hydratase, which is capable of inactivating epoxides[2–4]. However, with polycyclic hydrocarbons the situation is more complicated. If the epoxide groups are located on a benzo ring opposite a bay region, the resulting dihydrodiols are precursors of even more reactive dihydrodiol epoxides which readily bind to DNA[6], are often strongly mutagenic[7–10] and may be mainly responsible for carcinogenic effects of some polycyclic hydrocarbons[11]. Because, with the environmental carcinogen benzo(*a*)pyrene, epoxide hydratase was unable to inactivate these dihydrodiol epoxides[12,13], we have investigated the ability of a dihydrodiol dehydrogenase[14–16] to sequester the precursor dihydrodiols and thereby afford protection. To this end we have used bacterial mutagenesis[17] as the biological endpoint to investigate the metabolic activation of benzo(*a*)pyrene by microsomal monooxygenase. Unfortunately, the dihydrodiol dehydrogenase requires the same pyridine nucleotide cofactor as the monooxygenases, so that simple removal or addition of cofactors could not be used to study the role of this enzyme. Therefore purification of the enzyme was necessary. We show here that in metabolic situations where epoxide hydratase cannot protect against benzo(*a*)pyrene metabolite-evoked mutagenicity, pure dihydrodiol dehydrogenase reduces it. This demonstrates another factor which could contribute to differences in susceptibility to polycyclic hydrocarbon-mediated toxicity between various animal species, strains, sexes, organs and developmental stages, and to differences in potency of polycyclic compounds. This enzyme also provides an additional tool for studying the molecular mechanisms of chemical carcinogenesis.

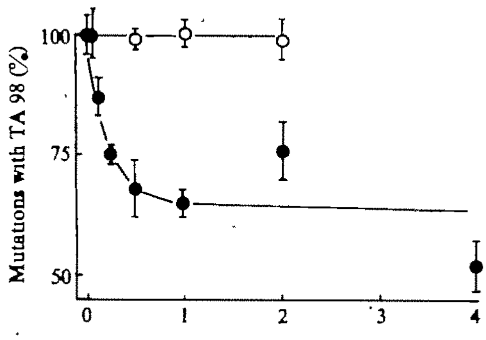

Fig. 1 Effect of dihydrodiol dehydrogenase on the mutagenicity of benzo(*a*)pyrene activated by liver microsomes from control (○) or 3-methylcholanthrene-treated (●) mice. Benzo(*a*)pyrene (5 μg, dissolved in 10 μl dimethylsulphoxide), 500 μl of a microsomal metabolising system (1 mg liver microsomal protein from adult male C3H mice, 2 mM NADP$^+$, 2 mM NADPH, 8 mM $MgCl_2$, 80 mM KCl, 50 mM Na phosphate, *p*H 7.4) 100 μl *his*$^-$ bacteria (1.7×10^8 *S. typhimurium* TA 98), various amounts of pure dihydrodiol dehydrogenase (in 100 μl 150 mM KCl) and 2,000 μl histidine-poor top agar (0.55% agar, 0.55% NaCl, 50 μM histidine, 50 μM biotin, 25 mM Na phosphate, *p*H 7.4, 45 °C) were mixed in a test tube and poured onto a minimal agar plate. After incubation for 3 d in the dark, colonies (*his*$^+$ revertants) were counted. Values are means ± s.e.m. of 3–10 parallel incubations.

Dihydrodiol dehydrogenase activity was measured by following the production of NADPH spectrophotometrically at 340 nm. The incubation, which was carried out at 37 °C, consisted of *trans*-1,2-dihydroxy-1,2-dihydrobenzene (1.8 mM), NADP$^+$ (2.2 mM), glycine buffer (50 mM, *p*H9.0) and the enzyme sample. One unit of enzyme activity was defined as the amount of enzyme which produced 1 μmol NADPH per min in these conditions. The 100,000*g* supernatant of liver homogenate of adult male Sprague–Dawley rats contained about 0.01 units dihydrodiol dehydrogenase per mg protein. The enzyme was purified about 500-fold with respect to rat liver 100,000*g* supernatant by a method which included ammonium sulphate precipitation, DEAE-cellulose chromatography, interfacial salting-in and gel filtration through Sephadex G-100. The preparation showed a single polypeptide band when analysed by SDS-gel electrophoresis and sedimented as a single symmetrical peak in the analytical ultracentrifuge in the absence of SDS. Refiltration through Sephadex G-100 resulted in a single protein peak of uniform specific activity. All these findings suggest that the preparations were homogeneous.

Fig. 2 Effect of dihydrodiol dehydrogenase on the mutagenicity of benzo(*a*)pyrene with or without simultaneous inhibition of epoxide hydratase. Adult male C3H mice received a single intraperitoneal injection of 3-methylcholanthrene (80 mg per kg body weight, dissolved in sunflower oil) 40 h before death. The livers were homogenised in three volumes 0.15 M KCl buffered with 10 mM Na phosphate, *p*H 7.4, the homogenate was centrifuged for 10 min at 10,000*g*, and the resulting supernatant fraction centrifuged for 1 h at 100,000*g* to give a microsomal pellet. Benzo(*a*)pyrene (5 μg, dissolved in 10 μl dimethyl sulphoxide), 500 μl of a microsomal metabolising system (1 mg microsomal protein), 1 unit glucose-6-phosphate dehydrogenase, 36 mM NADP$^+$, 15 mM glucose-6-phosphate, 8 mM $MgCl_2$, 80 mM KCl, 50 mM Na phosphate, *p*H 7.4), where indicated an epoxide hydratase inhibitor[26] (0.3 μl 1,1,1-trichloropropene 2,3-oxide) and/or 0.25 units dihydrodiol dehydrogenase (DH, dissolved in 100 μl 0.15 M KCl), 100 μl *his*$^-$ *bacteria* (1.7×10^8 *S. typhimurium* TA 98) and 2,000 μl histidine-poor top agar (0.55% agar, 0.55% NaCl, 50 μM histidine, 50 μM biotin, 25 mM Na phosphate, *p*H 7.4, 45 °C) were mixed in a test tube and poured onto a minimal agar plate. After incubation for 3 d in the dark, colonies (*his*$^+$ revertants) were counted. The number of revertant colonies in the absence of benzo(*a*)pyrene (38 colonies) was subtracted. Values represent means ± s.d. of 3 parallel incubations. Statistical significance was calculated with the Student's *t*-test; NS, not significant.

The effect of this pure enzyme on the mutagenicity of benzo(*a*)pyrene was studied in the microsome/*Salmonella* test[17]. In this test two metabolic pathways mainly contribute to the mutagenicity of benzo(*a*)pyrene[12]: (1) activation to benzo(*a*)pyrene-4,5-oxide[12,18] is predominant when liver microsomes from control animals are used; (2) dihydrodiol epoxides are mainly responsible for the mutagenicity when low doses of benzo(*a*)pyrene are activated by microsomes from animals in which cytochrome P448 is induced (by treatment with polycyclic hydrocarbons or with Aroclor 1254)[12]. In this situation simple epoxides again become the major mutagenic metabolites if epoxide hydratase is inhibited, or at benzo(*a*)pyrene concentrations which are high enough to inhibit

0028-0836/79/0277—0319$01.00

oxidation of the dihydrodiols. The *Salmonella typhimurium* strains TA 98 or TA 100 are highly susceptible to both groups of mutagenic metabolites, whereas the strain TA 1537 is much more susceptible to the 4,5-oxide than to the dihydrodiol epoxides[12].

Figure 1 shows the effect of dihydrodiol dehydrogenase in these two conditions. When benzo(*a*)pyrene was activated by liver microsomes from 3-methylcholanthrene-treated mice, addition of pure dihydrodiol dehydrogenase clearly reduced the mutagenicity. The effect increased with the dose of dihydrodiol dehydrogenase up to 0.5 units per plate; further addition of dihydrodiol dehydrogenase had no significant effect. Thus, maximal reduction of mutagenicity was achieved using about 15 times more enzyme than that present in the amount of liver equivalent to the microsomes used for activation. Similar, and even greater, differences in activities of foreign compound-metabolising enzymes are encountered between various animal species[19,20] or after exposure to foreign compounds with inducing properties[21,22].

The percentage of the benzo(*a*)pyrene mutagenicity which could be removed by dihydrodiol dehydrogenase depended on the bacterial strain. With TA 98, it was 30–60%, and with TA 1537, as expected from the lower sensitivity of this strain for benzo(*a*)pyrene dihydrodiol epoxides, it was smaller, 15–25% (data not shown). In contrast to these experiments with microsomes from 3-methylcholanthrene-treated mice, no effect of dihydrodiol dehydrogenase on the mutagenicity of benzo(*a*)pyrene was found when microsomes from control mice were used (Fig. 1). This is readily understandable, as control mouse liver microsomes activate benzo(*a*)pyrene mainly to benzo(*a*)pyrene-4,5-oxide rather than to dihydrodiol epoxides[12,18]. This is the metabolic situation where epoxide hydratase markedly reduced the mutagenicity[12,23]. Similarly, with 3-methylcholanthrene-induced microsomes in which the formation of dihydrodiols was prevented by inhibition of epoxide hydratase (Fig. 2), dihydrodiol dehydrogenase failed to reduce the mutagenicity of benzo(*a*)pyrene. The dihydrodiol dehydrogenase-resistant mutagenicity is probably due to simple epoxides[13,18,24,25], phenols[24,25] and metabolites of phenols[13] which are generated by the mammalian activating system.

Thus we conclude (1) that dihydrodiol dehydrogenase can protect against mutagenic effects of benzo(*a*)pyrene, but (2) that not all the mutagenic metabolites of benzo(*a*)pyrene can be removed by dihydrodiol dehydrogenase. (3) Probably due to the combination of a relatively efficient inactivation of other active metabolites of benzo(*a*)pyrene and the high inherent biological activity of dihydrodiol bay-region epoxides, the latter seem to play an especially important part in mutagenicity, DNA binding, cell transformation and tumour formation[8–11]. Therefore, the discovery that dihydrodiol dehydrogenase is capable of reducing the mutagenicity mediated by the dihydrodiol–epoxide pathway opens an intriguing perspective for the entire field of polycyclic hydrocarbon-evoked mutagenicity, carcinogenicity and cytotoxicity.

Conformation of Moloney murine leukaemia proviral sequences in chromatin from leukaemic and nonleukaemic cells

THE structure of transcriptionally active and inert regions of eukaryotic chromatin can be differentiated on the basis of their sensitivity towards nuclease digestion. Whereas DNase I preferentially digests transcriptionally active genes into fragments too small to form stable hybrids, micrococcal nuclease shows no preferential digestion of specific nuclear DNA sequences[1–6]. We report here experiments in which the structure of Moloney murine leukaemia proviral DNA sequences in chromatin of target cells expressing the viral genome and of non-target cells in which the same sequences are repressed were examined by digestion with DNase I and micrococcal nuclease. It is shown that the Moloney murine leukaemia virus (M-MuLV) genomes in target and non-target cells of BALB/Mo mice are integrated into the host cell genome and organised in nucleosome-like structures. The difference in transcriptional activity of viral genomes in target and non-target cells is reflected by a difference in DNase I sensitivity. A partial resistance to DNase I of M-MuLV sequences in target cells suggests that the multiple viral genome copies in these cells are integrated at different sites and have different transcriptional activity.

Retroviruses provide excellent model systems for studying the structure of eukaryotic chromatin. As endogenous viruses they are normal constituents of the genomes of a wide variety of animal species. Alternatively, they can integrate into the genome of their host organisms after exogenous infection where they serve as template for the transcription of viral mRNA and progeny genome RNA (refs 7, 8). The expression of the integrated retroviral genome is subject to control by genetic factors of the host[9] and is linked to the differentiated state of the infected cell[10]. Thus, these viruses offer the unique opportunity for studying the structural organisation of well defined DNA sequences in various states of expression.

The experiments described here were carried out with nuclei isolated from different organs of BALB/Mo mice and therefore reflect the state of proviral DNA sequences in the animal. BALB/Mo mice were derived from an animal infected at the four- to eight-cell preimplantation stage with M-MuLV. They carry the M-MuLV genome integrated into the DNA of all organs and transmit it like an endogenous virus[11,12]. The genetically transmitted viral structural gene, the *Mov-1* locus, has recently been assigned to mouse chromosome 6 (ref. 13). BALB/Mo mice develop a specific, thymus-derived leukaemia. Expression of the M-MuLV genome during leukaemogenesis is restricted to lymphatic target tissues (spleen, thymus) and is

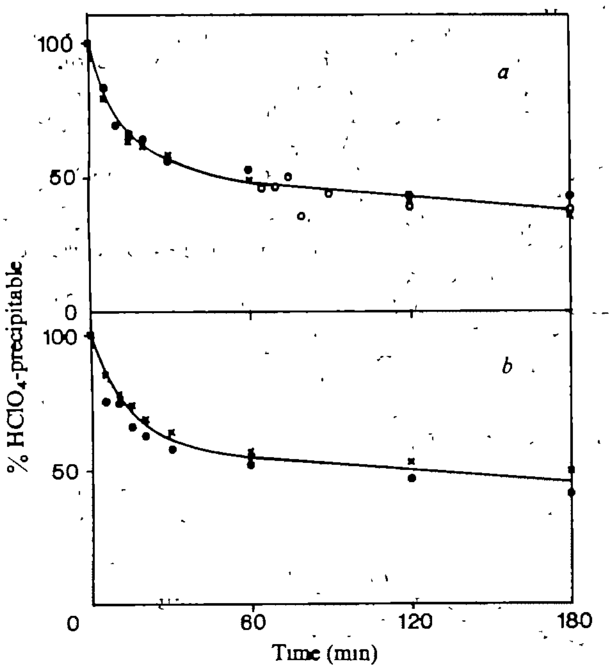

Fig. 1 Kinetics of digestion of mouse liver and spleen chromatin with *a*, DNase I, and *b*, micrococcal nuclease. Nuceli were isolated from homogenised mouse tissues by centrifugation through 2.2 M sucrose and digested at 37 °C at a nuclear DNA concentration of 1 mg ml^{-1}. Enzyme concentrations were 10 units ml^{-1}. The percentage of DNA remaining $HClO_4$-precipitable was determined by precipitation with cold 7% $HClO_4$ and subsequent measurement of the absorbance at 260 nm of the acid-soluble and insoluble fraction. ●, Spleen nuclei; ×, liver nuclei; ○, fresh enzyme was added after 1 h.

correlated with a somatic amplification of viral DNA sequences[11,14]. In contrast, the viral genome remains repressed throughout the life of the animals and no amplification of viral sequences occurs in non-target organs (such as liver or brain)[14].

We have carried out DNase I and micrococcal nuclease digestions of chromatin from target (spleen) and non-target (liver) cells of homozygous[12] leukaemic BALB/Mo mice. The conditions of digestion with both enzymes were chosen to render approximately 50–60% of the DNA $HClO_4$-soluble within 60 min. Further incubation or the addition of fresh enzyme did not significantly increase the $HClO_4$-soluble fraction, indicating that the undigested fractions were resistant to the action of the enzymes (Fig. 1). These results confirm the findings of others[1]. After different periods of DNase digestion, aliquots were withdrawn and the DNA was purified and analysed for M-MuLV-specific sequences by a quantitative complementary DNA excess hybridisation using an M-MuLV-specific cDNA which does not recognise endogenous virus sequences[12,15]. As shown in Fig. 2*a*, M-MuLV-specific sequences were preferentially digested by DNase I in spleen cells of homozygous leukaemic BALB/Mo mice: whereas undigested DNA from these cells contained three to four M-MuLV genome copies per haploid mouse genome equivalent, this number was reduced to approximately two copies after digestion with DNase I for only 10–15 min. This was not observed in liver cells from the same animals: liver cells contained one viral genome copy per haploid mouse genome, which was not preferentially digestible by DNase I (Fig. 2*a*).

The preferential digestibility by DNase I of M-MuLV-specific sequences in chromatin from spleen but not from liver cells of homozygous BALB/Mo mice agrees with the finding that the viral genome, although genetically transmitted and present in every cell of these mice, is expressed only in 'target' organs such as spleen and thymus, whereas it stays repressed in 'non-target' organs such as liver and brain[14]. However, as shown in Fig. 2*a*, in spleen cells of homozygous, leukaemic mice, in which an amplification of the viral genome from initially one to three to four copies per haploid genome had taken place, only two of the copies were sensitive to DNase I, whereas the remaining one to two copies showed the same relative resistance towards DNase I as the bulk of the host DNA sequences. In analogy to the findings of others[1–6], we assume that the DNase I-sensitive sequences are transcriptionally active, whereas the resistant ones are inactive. This assumption is supported by the preliminary finding that in young homozygous BALB/Mo mice which contain only one M-MuLV genome copy in their target cells[14], this single copy is sensitive to DNase I digestion.

The partial resistance of M-MuLV sequences to DNase I in spleen cells of homozygous, leukaemic BALB/Mo mice (Fig. 2*a*) therefore suggests a difference in the transcriptional activity of the various viral genome copies in leukaemic tissues. On the basis of these data, however, we cannot exclude a heterogeneity of the cell population in the sense that in some cells all M-MuLV sequences are DNase I-sensitive and in others all are resistant. Furthermore, as the complexity of the cDNA probe used in the hybridisation analysis has not been accurately determined[12] and nothing is known about the molecular organisation of the various M-MuLV genome copies integrated in leukaemic cells,

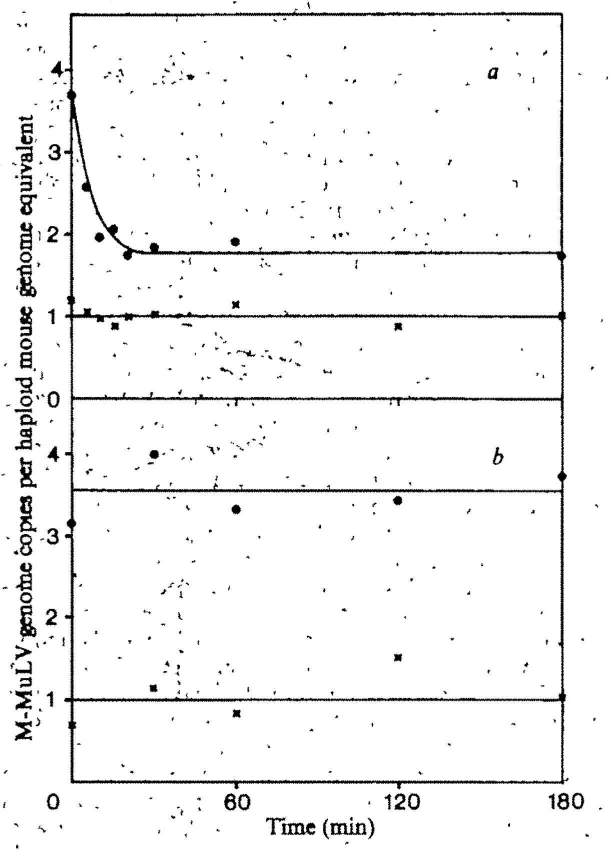

Fig. 2 Determination of M-MuLV-specific sequences in DNase-digested chromatin by molecular hybridisation. Nuclei from spleens (●) and livers (×) of homozygous leukaemic BALB/Mo mice were isolated and digested with *a*, DNase I, and *b*, micrococcal nuclease, as described in Fig. 1. After the times indicated, undigested DNA was extracted from the DNase-treated nuclei, purified by CsCl-ethidium bromide equilibrium centrifugation and boiled in alkali as described elsewhere[11,12]. The concentration of M-MuLV-specific DNA sequences was determined in each DNA preparation in a cDNA excess hybridisation assay using an M-MuLV-specific cDNA probe essentially as described elsewhere[12,15]. M-MuLV genome copy numbers were calculated by comparison with standard mouse DNAs with known contents of viral sequences (homozygous and heterozygous BALB/Mo embryo DNAs containing 1 and 0.5 M-MuLV copies per haploid mouse genome equivalent, respectively[12]). Thus, the ordinate represents M-MuLV genome copies per weight of undigested DNA expressed as haploid mouse genome equivalents.

Table 1. Hirt fractionation

DNA source	M-MuLV genome copies per haploid mouse genome	% Of total DNA in supernatant	% Of M-MuLV-specific DNA in Supernatant	% Of M-MuLV-specific DNA in Precipitate
Spleen	3.4	2.5	2.4	97.6
Liver	1.4	3.8	4.5	95.5
SV40	—	89.5	—	—

Mouse tissues were homogenised in a loose Teflon homogeniser in phosphate-buffered saline (PBS) (liver 5 ml PBS per g; spleen 20 ml PBS per g) The homogenate was diluted with 6 volumes of 10 mM Tris-HCl, pH 7.6, 10 mM EDTA, and the high molecular weight DNA was precipitated with 1% SDS and 1 M NaCl as described by Hirt[16] The precipitates were centrifuged (30 min, 27,000 g, 4 °C), DNA was extracted and purified from the supernatant and precipitate fractions, and M-MuLV-specific sequences were determined by molecular hybridisation[12,15]. In a control experiment, radioactively labelled SV40 DNA was added to a spleen homogenate to determine the degree of trapping and co-precipitation of free viral DNA with the Hirt precipitate.

we cannot determine whether parts or all of the viral genomes are in the sensitive configuration.

When similar experiments were carried out with micrococcal nuclease, we found that this enzyme did not preferentially digest viral sequences, in either target or non-target tissues, of leukaemic BALB/Mo mice (Fig. 2b): the relative concentration of viral sequences (three to four copies per haploid genome in spleen and one copy in liver cell chromatin) was constant throughout the course of digestion. This was observed reproducibly in organs from BALB/Mo mice of different age as well as in M-MuLV-producing fibroblasts *in vitro* (data not shown). This result indicates that the M-MuLV genomes in target and non-target organs of BALB/Mo mice, including the copies that are amplified during leukaemogenesis, are organised in similar nucleosomal structures to those of the host cell DNA, and suggests that the multiple viral genome copies in tumour cells are integrated into the host cell genome and not present as free proviral DNA.

To determine directly whether unintegrated proviral DNA contributed to the DNase I-sensitive fraction of the M-MuLV-specific sequences in the experiments described above, we fractionated the DNA from spleen and liver cells of leukaemic homozygous BALB/Mo mice by the Hirt procedure[16] and tested the supernatant and precipitate fractions for M-MuLV-specific sequences by molecular hybridisation. As shown in Table 1, only 3–4% of the total DNA from mouse liver or spleen cells was not precipitated by this procedure. In contrast, when radioactively labelled SV40 DNA was added before the fractionation, almost 90% of the radioactivity was found in the supernatant, eliminating the possibility that unintegrated proviral DNA was trapped and co-precipitated with the cellular DNA. When the Hirt supernatant and precipitate fractions were analysed for M-MuLV-specific sequences, we found that 96% in liver chromatin and 98% in spleen chromatin of the virus-specific DNA was precipitated with the high molecular weight cellular DNA, showing that virtually all the viral sequences are in an integrated state and that only very little, if any, free proviral DNA is present. A similar conclusion was reached by Berns *et al.* (personal communication) on the basis of restriction enzyme analysis of DNA from liver and leukaemic cells from BALB/Mo mice which indicate that the somatic amplification of M-MuLV involves new and independent integration sites.

We have shown here that M-MuLV-specific sequences in chromatin from target and non-target organs of BALB/Mo mice have a different conformation as reflected by a difference in DNase I sensitivity. This confirms that changes in transcriptional activity of eukaryotic genes correlate with conformational changes of the respective chromatin regions[1–6]. In M-MuLV and AKR virus-induced leukaemia of mice, leukaemogenesis is accompanied by a somatic amplification of virus-specific sequences[11,14,15]. The studies reported here have shown that the multiple viral genome copies in leukaemic cells are integrated into the host cell genome and that the integrated viral sequences are organised in nucleosomal structures. The partial resistance to DNase I of M-MuLV-specific sequences in leukaemic cells (Fig. 2a) agrees with the hypothesis that the viral genome copies integrated at different integration sites have different transcriptional activity. Dino and Penhoet[17] have recently come to a similar conclusion by measuring intracellular concentrations of viral RNA in murine leukaemia virus and sarcoma virus-infected cells. It will be of interest to characterise further the various integrated M-MuLV genome copies in leukaemic cells and to correlate the different integration sites to transcriptional activity and leukaemic transformation.

Simian virus 40 specific proteins on surface of HeLa cells infected with adenovirus 2–SV40 hybrid virus Ad2$^+$ND2

CELLS infected or transformed by simian virus 40 (SV40) express SV40 tumour-specific transplantation antigen (TSTA)[1,2]. The mechanism of tumour rejection mediated by this antigen is not yet understood, but our knowledge about transplantation rejection suggests that TSTA should be located on the cell surface[3]. SV40 TSTA has a close molecular relationship to SV40 T-antigen[4,5], which is a nuclear antigen, and until now, SV40 specific proteins have not been demonstrated unequivocally in the plasma membranes or on the cell surfaces of SV40 infected or transformed cells. In contrast, in cells infected by the nondefective adenovirus 2–SV40 hybrid virus Ad2$^+$ND2, a virus known to induce SV40 TSTA[6] the SV40-specific proteins (MW 56,000 (56K) and 42,000 (42K)) are stably incorporated into the plasma membranes[7]. These proteins are coded for—at least in part—by the SV40 portion of the hybrid virus genome and correspond to the C-terminal half of SV40 T-antigen[8]. Furthermore, these proteins are immunoprecipitable from extracts of Ad2$^+$ND2-infected cells using serum from SV40 tumour-bearing hamsters[7]. Analysis of Ad2$^+$ND2-infected HeLa cells by immunofluorescence microscopy for cell surface fluorescence using hamster SV40 tumour serum, however, failed to give a positive result (W.D., unpublished). A possible

0028-0836/79/0277—0322$01 00

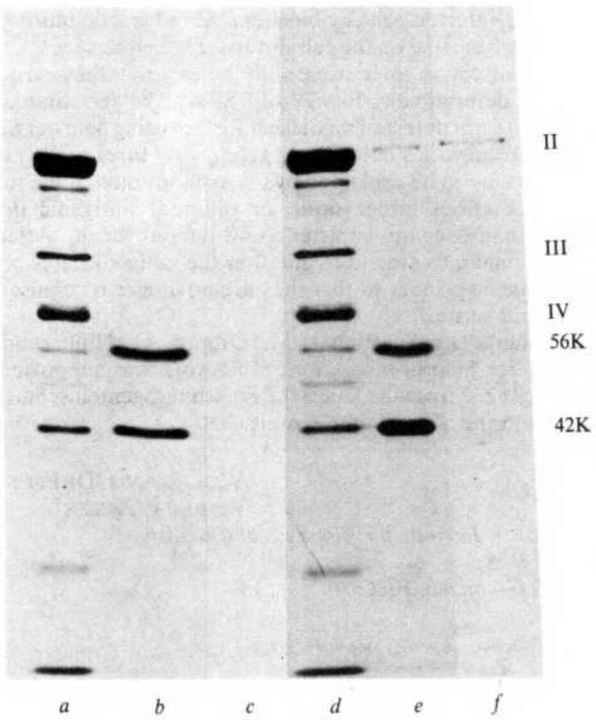

Fig. 1 Immunoprecipitation of SV40 specific proteins from NP40 cytoplasmic extracts of Ad2$^+$ND2–infected HeLa cells using hamster SV40 tumour serum or rabbit anti-T serum. HeLa cells grown in suspension were infected with Ad2$^+$ND2 and labelled from 40–41 h post-infection with ^{35}S-methionine (20 μCi ml^{-1}). NP40 cytoplasmic extract was prepared by lysing the cells with RSB[15] containing 0.5% NP40, and removal of the nuclei by centrifugation (800*g* for 5 min). Aliquots of 300 μl of the NP40 cytoplasmic extract were incubated with 30 μl of serum for 1 h at 0 °C and 150 μl pre-swelled protein A–Sepharose were added per assay and the reaction mixture was incubated for a further 30 min at 0 °C. The protein A–Sepharose containing the immune complexes was removed by centrifugation. The protein A–Sepharose was washed extensively with isotonic Tris buffer, *p*H 7.2, containing 0.2% NP40. Then the immunoglobulins were eluted from the protein A–Sepharose with 500 μl of 50 mM NH_4HCO_3, containing 1% SDS. The eluates were lyophylised and samples of the NP40 cytoplasmic extract (original reaction mixture), and the eluates were processed for SDS-PAGE analysis as described elsewhere[16]. Samples containing ~15 μg of protein were run on a 8.5% SDS-polyacrylamide gel and radioactive polypeptides were visualised by fluorography as described by Bonner and Laskey[17]. The sample order is: *a*, Ad2$^+$ND2 cytoplasmic extract; *b*, same, eluate after immunoprecipitation with hamster SV40-tumour serum; *c*, same, eluate after immunoprecipitation with hamster non-immune serum; *d*, Ad2$^+$ND2 cytoplasmic extract; *e*, same, eluate after immunoprecipitation with rabbit anti-T serum; *f*, same, eluate after immunoprecipitation with rabbit non-immune serum.

explanation is that upon location on the cell surface the structure of these proteins is altered so that they are no longer recognised by the tumour sera. These sera are probably directed against native T-antigen released from the nuclei of necrotic tumour material. We therefore decided to prepare antisera against SDS-denatured T-antigen which are directed against the primary structure of T-antigen rather than against its native conformation. We report here that SV40-specific proteins can be visualised on the cell surface of Ad2$^+$ND2–infected HeLa cells by immunofluorescence microscopy using a rabbit anti-T serum, prepared against purified SDS-denatured T-antigen.

T-antigen was prepared by preparative immunoprecipitation of cell extracts of the hamster tumour line H 65/90 B (originally obtained from Dr V. Defendi) according to the method of Schwyzer[9] using hamster SV40 tumour serum and protein A–Sepharose. T-antigen was then further purified by preparative SDS-polyacrylamide gel electrophoresis (SDS-PAGE) and electrophoretic elution of the T-antigen band. The electrophoretically pure T-antigen preparation was used for immunisation of a rabbit. The method of preparation of purified T-antigen and the immunisation procedure will be described elsewhere (W.D. and R.P., in preparation). Rabbit anti-T sera have been prepared in similar ways previously[10,11]. Hamster SV40 tumour serum (from Dr R. Henning) and the rabbit anti-T serum were first characterised by determination of their T- and U-antibody titres on SV40-transformed mouse cells (clone SV101), on heat-treated SV101 cells[12] and on Ad2$^+$ND2-infected HeLa cells[13], respectively.

Table 1 shows that both sera exhibited similar T-antibody titres on SV101 cells and similar U-antibody titres both on heat-treated SV101 cells and on Ad2$^+$ND2-infected HeLa cells.

The specificity of both sera was further assessed by immunoprecipitation of extracts from Ad2$^+$ND2-infected cells and analysis of cell extracts and immunoprecipitates by SDS-PAGE. Figure 1 demonstrates that both sera specifically precipatated the SV40-specific 56K and 42K proteins.

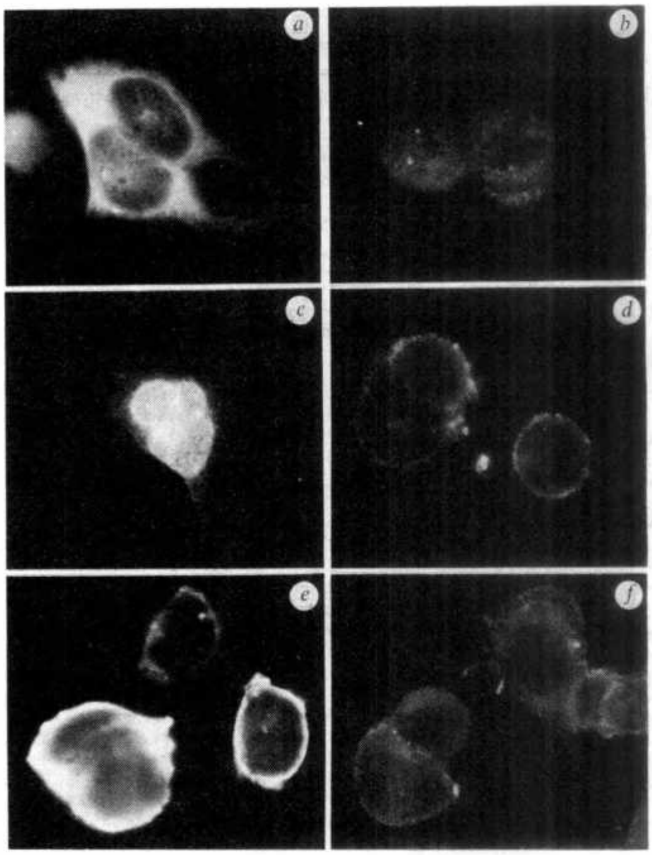

Fig. 2 Visualisation of SV40 specific proteins within and on the cell surface of Ad2$^+$ND2-infected HeLa cells by immunofluorescence microscopy. HeLa cells grown on coverslips (12 mm) were infected with Ad2$^+$ND2 (*a*, *c*, *d*, *e*) or Ad2 (*b*, *f*) and processed for immunofluorescence microscopy 40 h post-infection as described in Table 1 legend. Cells in panels *a*, *b* and *c* were fixed by methanol–acetone treatment as described in Table 1 legend, cells in panels *d*, *e* and *f* were fixed for cell surface staining by treatment for 5 min with 3.7% formalin in PBS at 0 °C followed by air drying. Cells in panels *a*, *b*, *e* and *f* were stained with rabbit anti-T serum, at a 1 : 100 dilution (panels *a*, *b*) or a 1 : 10 dilution (panels *e*, *f*) with PBS. Cells in panels *c* and *d* were stained with a rabbit antiserum prepared against purified HeLa cell nuclei. Cells were viewed with a Zeiss microscope equipped with epifluorescent illumination. Note that the uninfected cell in (*a*) (lower right) does not exhibit fluorescence staining. Cells in (*e*) are located in different focal planes. The cell in the middle right area is focused at the cell periphery, the focal plane of the island of two cells in the lower left being slightly above this. The cell in the upper middle area is either uninfected or in a very early stage of infection. Staining of either Ad2- or Ad2$^+$ND2-infected HeLa cells with rabbit non-immune serum did not result in immunofluorescence staining (data not shown). Photographs were taken with a Planapo 63 oil-immersion objective. Exposure times for panels *a*, *c* and e were ~30 s, for panels *b*, *d* and *f* ~2.5 min. Magnification in all panels is ~×366.

The rabbit anti-T serum described above was then used to analyse Ad2$^+$ND2-infected HeLa cells by immunofluorescence microscopy. Methanol–acetone fixation and staining with the rabbit anti-T serum and FITC-labelled sheep anti-rabbit-IgG revealed typical perinuclear or cytoplasmic U-antigen fluorescence[13] in the Ad2$^+$ND2-infected cells (Fig. 2*a*). This U-antigen fluorescence was found in about 80% of the cells, indicating that about this proportion of the cells were infected by Ad2$^+$ND2. Ad2-infected HeLa cells treated with rabbit anti-T serum, on the other hand, did not exhibit any fluorescence staining (Fig. 2*b*). Staining of living Ad2$^+$ND2-infected HeLa cells for cell surface fluorescence was impractical, because late in infection (~40 h) these cells are fragile and tend to lyse during processing for immunofluorescence microscopy. Analysis of Ad2$^+$ND2-infected cells for cell-surface fluorescence, therefore, was performed with formalin-fixed cells[18]. This treatment stabilises the cells and is believed not to render the cell membrane permeable to antibody. This was tested by analysing Ad2$^+$ND2-infected HeLa cells after methanol–acetone and after formalin fixation with an antiserum prepared against purified HeLa cell nuclei. Figure 2 demonstrates that this serum stained the nuclei in methanol–acetone fixed cells (Fig. 2*c*), but not in formalin-fixed cells (Fig. 2*d*). This result demonstrated that after formalin fixation antibody was no longer able to permeate the plasma membrane of the hybrid virus-infected cells. Staining of formalin-fixed Ad2$^+$ND2-infected HeLa cells with rabbit anti-T serum resulted in typical cell surface fluorescence of approximately 80% of the cells (Fig. 2*e*). This indicated that the cell surface fluorescence was associated with the Ad2$^+$ND2-infected cells. It was not visible on Ad2-infected HeLa cells (Fig. 2*f*), or when rabbit non-immune serum was used as first antibody (data not shown).

Table 1 T and U antibody titres of hamster SV40 tumour pool serum and rabbit anti T-serum

Sera	Antibody titres on SV101 cells (T-Ag)	Heated SV101 cells (U-Ag)	Ad2$^+$ND2-infected HeLa cells (U-Ag)
Hamster pool	3,200	800	600
Rabbit anti-T	1,600	1,600	600

Hamster SV40 tumour pool serum and rabbit anti-T serum were tested by immunofluorescence microscopy for T and U antibodies on SV101 cells and Ad2$^+$ND2-infected HeLa cells grown on coverslips (12 mm diameter), respectively. U antibody titres on SV101 cells were determined after heat inactivation of T-antigen[12] SV101 cells grown on coverslips (12 mm) were washed twice with phosphate-buffered saline (PBS)[14] and incubated in a wet chamber at 50 °C for 30 min. The cells were then washed twice with PBS and processed for immunofluorescence microscopy. SV101 post-infection cells, heat-treated SV101 cells and Ad2$^+$ND2-infected HeLa cells (at ~40 h.p.i.) were fixed by treatment with methanol at −20 °C for 5 min, followed by acetone treatment at −20 °C for 30 s and air drying. The cells were then incubated for 45 min at 37 °C with the first antibody (hamster SV40 tumour pool serum or rabbit anti-T serum) at the serum dilutions indicated. After washing extensively with PBS, the second antibody (FITC-labelled γ-globulin prepared against hamster IgG or FITC-labelled γ-globulin prepared against rabbit IgG, respectively) was added and the cells held for a further 45 min at 37 °C. After a second series of washes with PBS the coverslips were mounted with Elvanol on microscope slides. The cells were viewed with a Zeiss microscope equipped with epifluorescent illumination. Antibody titres are given as reciprocal of the serum dilution, at which the staining intensity was 1+ on a scale of 4+ = brilliant, and ± = very dull. Before use all sera were absorbed either on methanol-fixed 3T3 cells (when tested on SV101 cells) or on methanol-fixed, Ad2-infected HeLa cells (when tested on Ad2$^+$ND2-infected HeLa cells).

Staining of Ad2$^+$ND2-infected cells for surface fluorescence was positive with the rabbit anti-T serum down to a serum dilution of 1:100. However, when Ad2$^+$ND2-infected cells were tested for cell surface fluorescence using the rabbit anti-T serum after extensive absorption on methanol-fixed SV101 cells, a procedure which resulted in an 80% reduction of both the T and U antibody titres in this serum, no cell surface fluorescence could be obtained at a 1:10 dilution of the absorbed serum (data not shown). This result is further evidence for the SV40 specificity of the cell surface staining shown in Fig. 2*e*.

The cell surface staining of Ad2$^+$ND2-infected cells described above provides evidence that at least part of the SV40-specific 56K and 42K proteins located in the plasma membranes of Ad2$^+$ND2-infected cells by biochemical cell fractionation procedures[7] are located on the cell surface. The cell surface location of these proteins is compatible with the idea that they carry the antigenic determinants for SV40 TSTA. The fact that these proteins are not detected on the cell surface using hamster SV40 tumour serum with similar T and U antibody titres as the rabbit anti-T serum can be explained by the assumption that the rabbit serum recognises either more or different antigenic determinants than does the hamster SV40 tumour serum. Alternatively, formalin treatment might alter the antigenic sites of the SV40-specific protein so that they are no longer recognised by the tumour serum.

We thank Drs K. Weber, M. Osborn, G. Hiller and R. Henning for helpful discussions. This work was supported by grant De212/2 from the Deutsche Forschungsgemeinschaft and funds from the Max-Planck-Gesellschaft.

Eukaryotic DNA fragments which act as promoters for a plasmid gene

TRANSCRIPTION is the process that occurs in all organisms whereby the genetic information coded by the nucleotide sequences of DNA is transferred into RNA. This process is initiated by attachment of RNA polymerase to a region of the DNA called the promoter[1]. Considerable information has accumulated recently concerning the structure and function of prokaryotic promoters, but little insight has been gained into the characteristics of eukaryotic promoters. We report here on experiments that use an *E. coli* plasmid with an attenuated promoter as a probe for possible eukaryotic promoters.

The *E. coli* plasmid pBRH3B is a 5.2 megadalton derivative of pBR316 (ref. 2) which codes for ampicillin (Ap) and tetracycline (Tc) resistance. It was constructed by inserting a chemically synthesised *Eco*RI linker into the RNA polymerase binding site (that is, the promoter) of the Tc-resistance gene, thereby decreasing the Tc resistance conferred by the plasmid from 75 μg ml^{-1} to 5 μg ml^{-1} Tc (ref. 3). Insertion of a fragment of DNA at the *Eco*RI site completely abolishes the residual activity of the resident Tc promoter, and expression of Tc resistance then becomes dependent on 'foreign' promoters contained within the inserted fragments. The level of Tc resistance thus provides a simple biological assay for the presence and possibly the strength of promoter activity carried on cloned fragments.

Purified DNAs from several prokaryotic and eukaryotic organisms (Table 1) were digested with the restriction endonuclease *Eco*RI and cloned into the *Eco*RI restriction site

Table 1 Frequency of promoter active recombinants, expressed as percentage of total recombinants

DNA source	%
E. coli bacteriophage T4	25.3, 26.2
Escherichia coli	29.3
Bacillus subtilis	25.0
Rhizobium japonicum	9.8
Euglena chloroplast	33.0
Saccharomyces cerevisiae	27.4, 28.4
Tetrahymena thermophilia	7.57
Neurospora crassa	4.74, 4.65
Drosophila melanogaster	0.77, 0.84
Megasilia scalaris	0.23

Purified DNAs from each of the organisms listed above were digested with *Eco*RI, combined with an equimolar amount of *Eco*RI-digested pBRH3B, and incubated with T4 DNA ligase[2]. The ligation mixture was transformed into the *E. coli* strain RR1 and the cells were grown for three generations (3 h) at 37°C in Luria broth (LB) after which 0.1 ml aliquots were spread on LB plates containing 20 μg per ml Ap. Frequencies of total recombinants and of promoter-active recombinants were obtained for each species of DNA by patching 500–2,000 Ap-resistant colonies onto plates containing 5, 10, 15, and 20 μg per ml Tc. Those which did not grow on 5 μg per ml Tc were scored as Tc sensitive, those growing on 5 μg ml^{-1} but no higher, as non-recombinant plasmid vehicles, and those forming colonies on higher than 5 μg per ml Tc were categorised as recombinants exhibiting promoter activity. In cases where more than one frequency is indicated, the experiment was repeated and both results are listed. In every instance the remainder of the transformation mixture was plated onto plates containing 10 μg per ml Tc and 20 μg per ml Ap in order to select only those recombinants demonstrating Tc resistance greater than the plasmid vehicle. By spreading an aliquot of the cells on Ap plates alone at the same time, we could determine the proportion of transformants represented by these promoter-active recombinants. Based on the data obtained from patching the Ap-resistant transformants, we calculated the percentage of total recombinants which showed promoter activity. The results obtained were comparable with those listed in table 1. Since each experiment was carried out in identical conditions with respect to amounts of DNA used and time of incubation after transformation, it was not necessary to adjust the data for such factors as selective advantage, sibling production and genome size.

of pBRH3B. Ampicillin resistant transformants of *E. coli* were selected and then examined for increased levels of Tc resistance. We collected a series of recombinant plasmids for each type of DNA cloned which expressed Tc resistance levels ranging from complete Tc sensitivity, to resistance greater than 5 μg ml^{-1} Tc.

For each experiment, the percentage of recombinants which exhibited Tc resistance was calculated (Table 1), and DNA from 5% of the recombinants was purified so that the presence of a foreign DNA fragment in pBRH3B could be verified by *Eco*RI digestion and agarose gel electrophoresis. A wide range of fragment sizes was observed, but no correlation between the Tc resistance levels and the sizes of the DNA fragments were found. It is evident from the data in Table 1 that the frequency of cloned promoter active fragments in pBRH3B is reproducible and depends on the origin of the DNA. Moreover, the data suggest that both yeast and *Euglena* chloroplast DNAs may harbour nucleotide sequences similar to the promoter regions present in prokaryotic DNAs. The low frequency of promoter fragments cloned from *Neurospora* and *Drosophila* DNAs stands in marked contrast to the yeast and chloroplast frequencies, and suggests that the nucleotide sequences of *Neurospora* and *Drosophila* may have evolved further from the prokaryotes than those of *Saccharomyces* or *Euglena* chloroplast DNA. Since most promoter regions sequenced thus far are usually (A+T)-rich[1], the low frequency of promoter fragments obtained from *Rhizobium* DNA in comparison with those of the other prokaryotic DNAs may be explained by the unusually high (G+C) content (64%) of *Rhizobium japonicum* 110 (ref. 4).

It is not yet certain that the regions on the eukaryotic fragments which are recognized by *E. coli* RNA polymerase are *bona fide* eukaryotic promoters. Nevertheless, preliminary indications that *E. coli* RNA polymerase can recognise eukaryotic promoter sequences come from studies involving the cloning of the *Eco*RI fragment carrying the yeast 5S rRNA gene[5] into the *Eco*RI site in pBRH3B. This fragment exhibits strong promoter activity, as manifested by the high level of Tc resistance conferred by the recombinant. When the orientation of the fragment in the plasmid is reversed, resistance to Tc disappears (unpublished observation). This observation could be explained if one presumes that one end of the *Eco*RI 5S fragment carries a promoter which can effect transcription of the Tc resistance gene. The notion that eukaryotic DNA sequences can serve as promoters in *E. coli* is further supported by studies in which functional expression of eukaryotic genes in *E. coli* was obtained. The *Neurospora crassa* gene, 5-dehydroquinate hydrolase (qa-2$^+$), when cloned in the plasmid pBR322, can complement the *E. coli* mutation, *aro*D6 (ref. 6). Moreover, similar results have been obtained with the yeast gene *his*3, which has also been cloned by complementation in *E. coli*[7]. The fact that expression of the *Neurospora* (S. R. Kushner, personal communication) and yeast[7] genes in *E. coli* is independent of the orientation of the restriction fragment, suggests that transcription is being initiated by *E. coli* RNA polymerase at some point on the eukaryotic DNA and not by a plasmid promoter.

Previous efforts to identify eukaryotic genetic control signals by probing native or reconstituted chromatin with *E. coli* RNA polymerase have yielded mostly equivocal results. The experiments described here, however, offer an *in vivo* alternative to traditional *in vitro* modes of examining eukaryotic DNA. The fact that this approach does not require the functional expression of cloned genes makes it more desirable than cloning eukaryotic genes by the complementation of *E. coli* mutations. We feel that this kind of analysis will be useful for the isolation and characterization of promoters from organisms other than *E. coli*. The strength and number of promoter active fragments cloned can be affected by many factors, so it is possible that: (1) Tc resistance levels do not accurately reflect promoter efficiency and (2) due to sibling production, the percentage of promoter active fragments shown in Table 1 may only approximate the real percentage of *Eco*RI fragments carrying promoter active sequences. It is the relative frequencies of promoter active fragments which make this system amenable to the study of the evolution of regulatory sequences from prokaryotes to eukaryotes. Indeed, the frequencies of promoter active fragments obtained from *Saccharomyces* and *E. coli* DNAs suggest a degree of relatedness greater than might be expected for two protists separated by the prokaryote–eukaryote phylogenetic barrier. To try to gain further support for this analytical approach, we are extending this survey to include DNAs from additional prokaryotic and eukaryotic organisms.

We thank B. Butler, R. Doi, R. Jefferson, J. Mielenz and R. C. Tait and G. Wilson for various DNAs and M. M. Green for helpful discussions. This work was supported in part by the Upjohn Corporation and was carried out in accordance with the NIH Guidelines for Recombinant DNA Research.

Viking Mars labelled release results

THE labelled release (LR) Mars experiment[1,2] yielded a positive response from Mars soil when a radioactive organic solution was added and a negative response when the soil was heated to sterilisation temperature. After storage of the soil at 10 °C for two to three months in the spacecraft, there was almost no response on addition of radioactive nutrient[3].

Nussinov *et al.*[4] proposed that LR Mars life-detection response arose from water-induced outgassing of CO_2 from Mars surface fines. They state that the kinetics of outgassing in LR and GEX are similar and that the characteristic time of the yield of O_2 in GEX and CO_2 in LR are also similar.

We are surprised that they ignored the fact that the CO_2 released by the LR is radioactive and, therefore, must have arisen from the radioactive nutrient added to the soil sample. Further, we do not agree that the reaction kinetics in GEX and LR are similar. GEX outgassed all of the measured O_2 in ~2 h whereas the half-time for the LR production of radioactive CO_2 was ~8 h, after which production tapered off, but continued slowly, for the duration of the particular experiment (up to 90 Sol).

Although we are not yet certain whether the LR response was biological or chemical, we are sure that it cannot be explained by the outgassing of CO_2 trapped in Mars surface fines.

4. Nussinov, M D, Chernyak, Y B & Ettinger, J L. *Nature* 274, 859–861 (1978)

NUSSINOV *ET AL* REPLY—We should like to correct here a false impression that our paper[1] contained a conclusion about registration in the LR experiment of 'CO_2 trapped in Mars surface fines'. We assumed that due to the radioactivity of the $^{14}CO_2$, such a conclusion could never be drawn either by us or by readers. No conclusion as such can be made about the origination mechanism of the registered gases on the basis of the GEX and LR kinetics. It is only natural to think that $^{14}CO_2$ resulted from interaction between nutrient and O_2, the latter developing from the soil's reaction with water. The time trend of the count curve is typically filtrational which means that the formation of O_2 was rapid as compared with its transport. From a classical physical viewpoint, their kinetics implies quantitative similarity only of GEX and LR curve shapes, itself implying identity of the power dependence ($\sim t^{1/4}$ at small t) and exponential saturation ($t \rightarrow \infty$). Qualitative differences are easily explained by the fact that the very designs of GEX and LR were incorrect from the physical standpoint, namely: (1) shapes (and masses) of the GEX and LR samples were not identical; (2) specific quantity of nutrient differed in the experiments; (3) the most informative initial segments of the kinetic curves were not registered. These are the reasons that it was impossible to expect a better than order of magnitude agreement. Therefore the similarity of the GEX and LR kinetics should undoubtedly be considered as fact.

Note that the data by Levin and Straat on 'almost no response upon addition of radioactive nutrient' after storage of the soil at 10 °C for two to three months, are readily explained by our model. Indeed, O_2 physically adsorbed within the micropores at elevated temperatures can be converted to a chemisorbed state, thereby losing its reactability. At low Martian temperatures the chemisorption of O_2 is inhibited[1].

Mechanisms of sputtering

THE letter by Pollitt *et al.*[1] on sputtering makes an interesting suggestion but also several incorrect assertions about the adequacy of existing theories and ignores other publications.

In currently accepted theories of the sputtering of metals the incident ion generates collision cascades amongst the target atoms[2,3]. If these intersect the surface, atoms receiving more than a binding energy E_b, related to the heat of sublimation, may be ejected and appear with a characteristic energy distribution having a peak at $E_b/2$ and falling off as E^{-2} at high energies of ejection E. Integration of the distribution leads to the total sputtering yield which is inversely proportional to E_b and directly proportional to the energy deposited by the incident ion in generating atomic recoils near the surface. In a crystal the lattice imposes a structure on the spread of momentum in the cascade, focuses momentum into close packed directions and leads to anisotropic emission.

The cascade lasts for a very short time, of the order 10^{-13} s. Afterwards it leaves a local heating effect in a region known as the thermal spike which may persist for up to 10^{-11} s. In cases where the density of energy is high enough and the binding energy is low enough one expects sputtering by evaporation into a characteristic energy distribution, something like a maxwellian with a peak at a few tenths of an eV[4,5]. The spike temperature and hence the sputtering yield depends on the ambient temperature of the solid[6].

These two basic mechanisms are complementary to one another, not alternatives as Pollitt *et al.* seem to suggest. The cascade component usually dominates unless the solid is at a temperature approaching its melting point, the heat of sublimation is low or the bombarding ion is of such a mass and energy as to produce cascades of high energy density. The main observations are in accord with these predictions contrary to the assertions of Pollitt *et al.*[1]. The energy spectrum of sputtered atoms closely follows E^{-2} at high energies over many decades, generally has a peak at half the sublimation energy[2,7–11] and develops a low-energy peak near 0.1 eV when thermal spike conditions are fulfilled[2,12,13]. The total yield for various elemental targets with a fixed ion and energy is inversely proportional to sublimation energy. (The dependence on ion species for fixed target is a much more complex problem involving ion implantation phenomena)[14]. From single crystal targets anisotropic emission is observed[15–17] with angular widths[18–20] and energy distributions[2,21] consistent with momentum focusing effects. The measurements of yield over several decades of ion energy, when thermal spike conditions are not fulfilled, accurately follow cascade theory[3]. They definitely do not correlate with the energy deposited in electron excitation, which they should if the model proposed by Pollitt *et al.*[1] were operating.

In insulators, and particularly alkali

0028-0836/79/0277—0326$01 00

halide crystals, the characteristics of cascade and thermal spike mechanisms have also been seen[13]. But there is an additional mechanism at work which is related to electron excitation, because sputtering can be produced by low energy electrons and photons[22]. This has satisfactorily been explained[23,24] in terms of an exciton model in which a Cl_2^- ion is produced with anti-bonding orbitals which cause the sputtering, in common with the model of Pollitt *et al.*[1]. Unlike their idea it has been worked out in some detail and I am surprised they do not refer to it.

In the sputtering of adsorpates, molecular solids and polymers, experimental data are scattered. The fact that large molecular fragments are sputtered and the expectation that electronic relaxation times are relatively longer than in metals gives the model by Pollitt *et al.*[1] a better chance. An obvious test would be to search for correlation between sputtering yield and the electronic stopping power for the incident ion, perhaps by varying the ion energy over several decades straddling the energy where electronic stopping power is a maximum (say 10 keV–1 MeV H^+).

Tectonic emplacement of ophiolitic rocks in the Precambrian Mona Complex of Anglesey

THORPE[1] believes that the Anglesey serpentinite–gabbro suite should be regarded as part of an ophiolite—and therefore tectonically emplaced—because of alleged similarities with Tethyan ophiolites. The latter embrace a large and diverse collection of phenomena, so that it is hardly surprising that some parallels can be drawn. However, other features seem to have been misrepresented by Thorpe and critical differences neglected.

Apart from occurring on a scale quite minute in comparison with Tethyan and other ophiolites, the Anglesey suite (exposed not at Newborough, but near Rhoscolyn, grid ref. 277770) does not display the diagnostic properties of an ophiolite. For example, the serpentinite and gabbro show no semblance of a layered or sequential arrangement, there is no sheeted dyke complex, and although cherty sediments and pillowed basalts do appear on Anglesey they are distant, both geographically and stratigraphically, from the intrusive suite.

Thorpe asserts that aspects of the Anglesey suite such as 'finely preserved igneous textures' near margins, and 'absence of evidence for regional thrusting' are of 'widespread occurrence' in many tectonically-emplaced ophiolite complexes'. It seems to me that many ophiolites (see ref. 2) are characterised by a peripheral tectonite fabric, at least at the basal margin, and that geological maps of ophiolite terrains are replete with thrusts.

I disagree that the suite 'provides evidence of local rapid uplift, erosion and transport'. The country rocks are, on all sides, the same, distinctive, deep-water lithology which constitutes much of West Anglesey. Debris from the suite is not found (unlike Tethyan instances). The melange (olistostrome) occurring elsewhere on Anglesey evinces such processes arising later, but it also seems to contain no fragments of the serpentinite–gabbro suite, which may have still been at depth.

I have agreed[3] that the overall Monian association suggests an ultimate oceanic or upper mantle origin for the suite, but unfortunately the geochemistry cited by Thorpe reveals nothing about how the material was emplaced. A comparison with other, such as Tethyan, ophiolites would imply emplacement by obduction, although Thorpe seems to envisage some (unspecified) mechanism associated with plate subduction. The field evidence is most compatible with the suite being a deformed magmatic peridotite–gabbro complex.

Applying the fashionable soubriquet 'ophiolite' to the Anglesey suite requires a worrying stretching of the definition, and introduces serious implications for the stratigraphy and tectonics of the Mona Complex as a whole.

Extending the range of radiocarbon dating

THE letter from Hedges and Moore[1] on laser enrichment of ^{14}C and its application to radiocarbon dating describes a most interesting and valuable line of research deserving the acclaim of all concerned with late Quaternary studies. It may be worth pointing out, however, that their statement of their expectation that the laser enrichment and new mass spectrometric methods will allow radiocarbon dating to be applied "well into the last interglacial period"[1] begs a chronometric question for the dating of the last interglacial is not yet known with certainty. A more cautious and less pre-emptive statement might be to the effect that the new methods, by extending the far limit of radiocarbon dating to 100,000 years, may allow at least a part of the last interglacial to be absolutely dated. This is a different matter and in view of the importance of Hedges' and Moore's work the distinction is worth making clear at the outset.

HEDGES AND MOORE REPLY—The distinction made by Burleigh is well taken. In this context it should be pointed out that the absolute dating to which he refers can only be achieved after reliable calibration of the radiocarbon time scale for this period. Fortunately there are grounds for believing that corrections to the radiocarbon time scale will not be very large[1].

Failure to produce hepatic hyperplastic nodules in rats by portacaval anastomosis and testosterone

WEINBREN AND WASHINGTON[1] recently reported the spontaneous development of hyperplastic nodules in the livers of rats previously subjected to portacaval anastomosis (PCA). The nodules were found in all rats by 6 months post-operation. Others have failed to note such nodules in PCA rats and the authors suggested that this may be related to the difficulty in detecting the lesions microscopically or to differences in rat strains, housing or diet. We have examined 24 PCA rats 10–15½ months post-operation and have not found liver nodules. Because

Weight changes are those from beginning of testosterone treatment. P values are for comparison of treatment against control unless specified (PT–T, PT–P), using two-tailed t-test.

it is known that some androgens produce adenomas in humans[2] and facilitate the development of hyperplastic nodules in carcinogen-fed rats[3], we also tested the effect of testosterone (T) on PCA rats.

Male Wistar rats (Charles River) approximately 250 g were subjected to PCA or sham operation over a 2½-month period. Others were kept as controls. All were maintained on Purina rat chow Formulab and tap water *ad libitum* in wire bottom cages, four or five per cage. Five PCA rats killed 10 months after operation did not have nodules. Half of the remaining rats were given 200 mg testosterone enanthate (Delatestryl; Squibb) in sesame oil subcutaneously at monthly intervals for three doses. The other half received oil only (Table 1). There were six intercurrent deaths (two PCA, two PCA+T, two T); three of these animals were autopsied and found to be free of liver nodules. The remaining animals were killed one month after the last dose and 13½–15½ months (mean 14½) after operation. Under ether anaesthesia, Evan's blue in saline was injected into the spleen and the anastomosis was considered satisfactory if the liver did not darken within 10 s. Otherwise the animals were rejected from the study. Sham and control animals showed no significant difference and the data were pooled.

The livers were examined carefully for gross or microscopic nodules. None were found in any group. PCA decreased the body and liver weights and increased the spleen weights whether expressed as absolute or relative weight (% of body weight). Atrophy of zone III hepatocytes with an increased nucleo-cytoplasmic ratio in these cells compared to zone I cells was seen in 7 of 17 PCA±T rats. Scattered hepatocytes with larger vesicular nuclei and pale cytoplasm lacking the usual coarsely granular basophilia were seen in 8 of 17 PCA±T rats (Table 1). These cells were located in plates one cell thick and were not clustered to form nodules. The spleen in the PCA±T groups had follicles similar in size and character to those of controls but there were more lymphocytes and occasional plasma cells in the cords of the PCA spleens. Bladder calculi, often accompanied by pyelonephritis, were common after PCA.

Testosterone caused yellowing of the fur, gross enlargement of the seminal vesicles and a decrease in the body weights. There was a relative increase in liver weight in the PCA group and absolute as well as relative increase in kidney weight in both PCA and control groups.

PCA in this study induced liver atrophy but not hyperplastic nodules. Strain and dietary differences are likely explanations for the discrepancies between this work and that of Weinbren and Washington.

We thank Dr Fred Plum for the animals.

On codon usage

THE total nucleotide sequence of the *lac* repressor gene *I* (361 codons assigned) has recently been determined by Farabaugh[1]. He has found that the codon usage is quite different from that of bacteriophage MS2 and ΦX174 (1,068 and 1,346 codons assigned, respectively). Nevertheless, assuming that both the repressor protein and the phage proteins are synthesised rapidly, he concluded that the codon usage presumably does not reflect a difference in efficiency of translation. As mentioned also by Farabaugh, however, no firm data actually exist on the relative translational efficiency. Moreover, even a small effect, difficult to reveal by direct methods, can have a strong selective value when judged over many generations.

Bacteriophage MS2 produces a burst size of 5,000 to 10,000 plaque-forming units (PFU) per cell, and each virus particle contains 180 coat protein molecules. Consequently, we have argued before that MS2 has optimised translational efficiency, especially of the coat cistron: one of these ways, among others, is by the proper choice of degenerate code words[2,3]. It is likely that there exists an optimal interaction energy between the codon and the cognate anticodon. As a result, codons of the type (A/U)–(A/U)-Y—where the first and second letters give an intrinsically weaker interaction—would be stabilised if the third letter is C. Indeed, in MS_2RNA the N-N-C codon is preferred over N-N-U for all codons of this type (Phe, Ile, Tyr and Asn)[4]. Conversely, intrinsically strongly interacting codons of the type (G/C)–(G/C)-Y should be loosened by a preference for U. In fact, N-N-U codons are preferred over N-N-C for Pro, Ala and Gly (Arg codons are not included as they are recognised by an inosine-containing tRNA).

When we now consider the codon usage in the *lacI* gene, which makes the *lac* repressor protein at very low levels, we find exactly the opposite situation. U as a third letter is preferrable to C for codons of the weak interaction type (Phe, Ile, Tyr and Asn); this is remarkable, considering that of third letters 28.6% are C and only 21.1% are U. Conversely, for the codons with a strong interaction in positions 1 and 2, the third letter is preferably a C rather than a U (Pro, Ala, Gly). This selective pattern of codon usage in the two systems is very striking and it would be of considerable interest if it could be related to a difference in translational efficiency. Calos[5] has shown that the low level of *lacI* expression can be explained by a low-efficiency promoter; as pointed out by Müller-Hill *et al.*[6], one can also easily imagine that the low level of constitutive *I* expression is further reduced by some limiting step in the translation processes, such as selective codon usage.

Physics of Minerals and Inorganic Materials

An Introduction

Translated from the Russian by G. Egorova, A.G. Mishchenko

Solid-state theories and spectroscopy account for the third crucial change within this century in our concept of the basis of mineralogy and the inorganic materials sciences. This book is a revised, updated, and supplemented translation from the Russian edition, providing a complete system of recent theories of solids as they apply to minerals and inorganic materials. Both basic principles and sophisticated new theories are presented with the mineralogist and materials researcher in mind. The book contains extensive references for further study and will be a valuable reference work since each chapter is self-contained.

Contents: Quantum Theory and the Structure of Atoms.– Crystal Field Theory.– Molecular Orbital Theory.– Energy Band Theory and Reflectance Spectra of Minerals.– Spectroscopy and the Chemical Bond.– Optical Absorption Spectra and Nature of Colors of Minerals.– Structure and the Chemical Bond.– Chemical Bond in Some Classes and Groups of Minerals.– References.

Spectroscopy, Luminescence and Radiation Centers in Minerals

Translanted from the Russian by V.V. Schiffer, with the collaboration of the author

Progress in the research of minerals, lunar specimens, and inorganic materials has been greatly affected in the past decades by the introduction of solid-state spectroscopy methods. This book examines mineralogical applications of nuclear gamma-resonance (Mössbauer) spectroscopy, X-ray and electron spectroscopy, nuclear magnetic resonance and electron paramagnetic resonance. The luminiscence and thermoluminescence of minerals are considered on the basis of crystal field, molecular orbital and energy band theories, as well as EPR data. Models of electron-hole centers for many types of minerals and materials are treated extensively based on molecular orbital theories and EPR studies. Basic principles are outlined and experimental data surveyed in each chapter. The bibliography contains 1,023 references to papers and books published mostly between 1960 and 1970. A unique reference, this book breaks new ground in the earth sciences and presents heretofore largely inaccessible material.

Contents: Mössbauer (Nuclear Gamma-Resonance) Spectroscopy.– X-Ray and X-Ray Electron Spectroscopy.– Electron Paramagnetic Resonance.– Nuclear Magnetic Resonance (NMR) and Nuclear Quadrupole Resonance (NQR).– Luminescence.– Thermoluminescence.– Radiation Electron-Hole Centers (Free Radicals) in Minerals.– References.

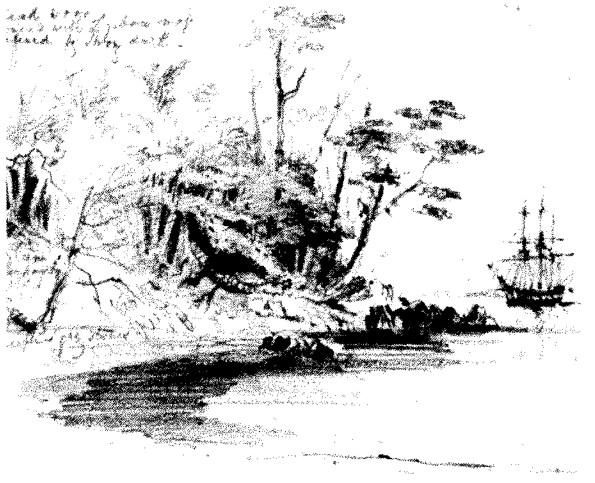
New books from CAMBRIDGE



The Beagle Record
Edited by RICHARD DARWIN KEYNES
This book tells the story of the voyage of H.M.S. Beagle round the world in 1831-1836, taken from letters of Darwin and FitzRoy, the captain of the Beagle, Darwin's diary and books published about the voyage in 1839. The text is beautifully illustrated with a selection from the original pictorial record produced by Conrad Martens, the Beagle's official artist. Much of the material included in the book is published here for the first time. This appealing book will be of interest to the general reader and to historians of art and science.
£30.00 net

Life Sciences in the Twentieth Century
GARLAND E. ALLEN
This book traces the shift from the descriptive to the experimental, laboratory-oriented approach to biology in the nineteenth century and shows how many modern areas of biology took their stimulus from - but ultimately broke away from - Darwinian methodology. This interpretative history will be of interest to students and teachers of the history of science.
Paperback £2.95 net
Cambridge History of Science Series

Handbook of Phycological Methods
Physiological and Biochemical Methods
Edited by J. A. HELLEBUST and J. S. CRAIGIE
The first compilation of biochemical and physiological procedures selected specifically for the experimental phycologist and supplied with practical examples of techniques applied to algae. The detailed descriptions of the methods used and the numerous technical suggestions will make this handbook invaluable to beginners and experts alike. **£18.00 net**

Transmission and Propagation of Electromagnetic Waves
K. F. SANDER and G. A. L. REED
The modern world relies on communications systems dependent on the transmission of information by electrical means. The detailed application of the underlying theory of electromagnetic waves to practical systems has advanced steadily, and the book presents those aspects of the theory which are directly relevant to the transmission of information in free space. This text is suitable for advanced undergraduates in electrical engineering or applied physics. **Hard covers £24.50 net**
Paperback £5.95 net

Dielectrophoresis
H. A. POHL
Over the past twenty years dielectrophoresis has become an important tool in mineral, colloidal and cellular biological studies. This volume gathers together, for the first time, current knowledge and applications of the technique. The biological applications are a particularly exciting aspect of the book, thus making it a stimulating text for research workers in the physical, medical and biological sciences.
£48.00 net
Cambridge Monographs on Physics

Semiconductors
Second Edition
R. A. SMITH
While the basic physics of semiconductors has remained virtually unchanged, the science and technology of semiconductors has advanced rapidly over the past decade with a number of striking developments. This text which provides a comprehensive and up-to-date account of the subject will be invaluable to advanced students and research workers in physics and electrical engineering.
Hard covers £27.50 net
Paperback £8.95 net

Information Representation and Manipulation in a Computer
Second Edition
E. S. PAGE and L. B. WILSON
The book first introduces the basic ideas of information and coding theory and discusses how single items of data are represented and manipulated in computers. The three main classes of data structures and the subjects of searching and sorting are dealt with. This second edition introduces new algorithms and adds further examples with hints on their solutions. **Hard covers £12.00 net**
Paperback £3.95 net

Nature/nurture between the Wars

William J. Schull

The Triumph of Evolution: American Scientists and the Heredity/Environment Controversy, 1900–1941. By Hamilton Cravens. (University of Pennsylvania Press: Philadelphia, 1978.) $17.50.

HAMILTON CRAVENS' *The Triumph of Evolution* describes the sequence of events in the United States between the two World Wars which he contends led to the resolution of the heredity–environment controversy. Whether, indeed, a resolution has occurred, as he asserts, may seem dubious to one who follows *Nature's* book pages and the controversy over the roles of nature and nurture in differences in intelligence, or whatever it is that intelligence tests measure. Resolution here, however, merely means the achievement of an agreement among natural and social scientists that nature and nurture are distinct but interdependent variables.

The central theme of this book is that the sudden increase in the last decade of the nineteenth century of experimental biology and psychology, aided by the emergence of the new graduate universities, fostered an academic professionalisation of these sciences which had and continues to have profound repercussions. It led to changes in educational emphases in these institutions and encouraged the development of the accoutrements of science which we now take for granted. Numerous professional societies and journals were born, and a scurry for research resources begun which persists unabated. Out of this process, Cravens maintains, came consensus. A little lamented casualty was social Darwinism, at least in its most strident forms, whose adherents waned as the new professionals grew in number.

A complicated, somewhat conjectural but nonetheless intriguing series of events and developments in anthropology, genetics, psychology and sociology is set forth to support this central thesis. Much of Cravens' argument emerges through an analysis of the actions and inactions of the prominent figures of the time in the aforementioned disciplines. Some of these individuals intrigue him more than others. Franz Boas is such a case, but Davenport, Morgan, Ross, Yerkes, Dewey, Watson, Thorndike and Cattell —to mention but a few others—have their moments of attention. The activities of these individuals and their students are often interpreted in terms of their ethnic, religious and social affiliations. Their contributions to their branches of science as well as their academic and social fates are briefly limned. Most are treated sympathetically with possibly Charles Davenport emerging as the most prejudiced, least principled and least qualified of the major personalities. Familiar lesser figures such as Madison Grant, Harry Laughlin and Henry Goddard receive short shrift as is their due. To these three are ascribed some of the more sordid chapters in the eugenics movement in the United States and rightly so.

Cravens' is not the first analysis of many of these events. Kenneth Ludmerers' *Genetics and American Society: A Historical Appraisal* (1972) and Mark Haller's *Eugenics: Hereditarian Attitudes in America Thought* (1963), for examples, trace many of the same developments, and often somewhat more thoroughly but from quite a different perspective. This book makes more of the events which were occurring in the new universities, their strivings for distinction among their peers, and the emergence of a scientific community in the New World not wholly dependent upon that in the Old for its directions and philosophy. It prompts thought on the unusual impact that a few forceful personalities may have upon a discipline; witness Boas' imprint on anthropology.

Cravens' analysis does not strike me as especially disputatious. It is thoughtful and built on a serious consideration of a variety of materials—biographies, letters, journals, society proceedings and the like. Few will be able to read *The Triumph of Evolution* and not be exposed to new facts or facets in this controversy. The geneticist will learn of the turmoil his science provoked in the social sciences, and should be able to appreciate positions which may have merely seemed obdurate in the past. Similarly the cultural anthropologist, say, should learn more of the history of twentieth-century genetics, and the origins of its collective perspective. All will be exposed to parallelisms of which most readers will have been previously unaware. Many will be tempted to read further, and the extensive notes with which the book concludes will prove invaluable.

This otherwise interesting and generally unexceptionable book is marred in my view by two shortcomings. First, it is unnecessarily repetitive. Much of the contents of the chapter "The New Biology" is repeated elsewhere. We are told, for example, on p24 of G. Stanley Hall's strengths and weaknesses as the President of Clark University and much the same material appears again on p65. Edward East receives similar double treatment on pp51 and 169. Others fare in like manner. There is moreover a tiresome repetition of labels which brings me to my second objection. *The Triumph of Evolution* is flawed by the frequent use of stereotypes of people and institutions. We read of the white, Anglo-Saxon, Protestant; the left-liberal; the gentle Quaker and the humble normal school. While these may be handy labels and often serve a useful, albeit pejorative purpose in political tracts, they seem out of place to me in an historical account of this nature. H. J. Muller, for example, is variously characterised as brilliant, a radical, a man with left-liberal tendencies. Most who knew him would accept all of these appellations as valid. But he could equally well have been described as an elitist, an uncommonly gifted investigator with an incredible biological intuition, or a teacher who could communicate the excitement he found in genetics to students and colleagues alike. But do any of these labels provide a compelling basis for characterising him as one who was "quite willing to tolerate the eugenics movement and to perhaps even support some of its goals so long as the movement appeared disinterested, scientifically credible, and dignified"? I'm not questioning the attribution but merely its justification on no more forceful evidence, seemingly than a series of labels. These are poor substitutes for a penetrating analysis of the man. ☐

William J. Schull is Director of the Center for Demographic and Population Genetics, University of Texas Health Science Center, Houston, Texas.

Microtubules

Microtubules. By P. Dustin. Pp. 452. (Springer: Berlin, Heidelberg and New York, 1978.) DM148; $74.

It is now fifteen years since Slaughterback first coined the term 'microtubule', and the literature has grown expodentially from a mere two papers in 1963 to several hundred per annum today. During this time, there have been intermittent review chapters and specialised monographs originating from symposia, but never a survey encompassing the whole field. Finally, Dustin has written a book which deals exclusively with microtubules, which should be in every library, and which will be obligatory reading for everyone interested in microtubules.

The first half of the book is primarily concerned with the structure and biochemistry of microtubules, the interactions between microtubules, and microtubule inhibitors, whereas the second half concentrates on aspects of cellular physiology in which microtubules have been implicated, such as movement, secretion, axonal transport, and of course, mitosis. The book is not without its faults: it is for example exclusively a summary of the extensive literature and is not a critical appraisal of the work. Furthermore, it has taken two years to produce since Dustin completed his search of the literature, and so inevitably many current ideas are absent. One example is that the book only briefly mentions microfilaments and lacks any discussion of a possible interaction between microfilaments and microtubules. As such it is interesting to see where we were at two years ago, in the same way that the author's earlier book (with Eigsti), *Colchicine*, is a fascinating account of the field a decade before the visualisation of microtubules. A more serious fault is the review of the literature concerning the biochemistry of microtubules and the kinetics of assembly/disassembly *in vitro*, which is superficial and which fails to relate the properties *in vitro* to the *in vivo* behaviour of microtubules, yet clearly our understanding of the role of microtubules in cellular events will develop from such comparative studies.

Finally, the book is written as a series of independent chapters, each with its own bibliography, with the consequence that it is difficult to search for specific references. Despite these reservations, this is a book that should be read by all cell biologists. **Roy Burns**

Roy Burns is Lecturer in the Biophysics Section of the Department of Physics, Imperial College, University of London, UK.

Autoimmunity

Autoimmunity: Genetic, Immunological, Virologic and Clinical Aspects. Edited by N. Talal. Pp 734. (Academic: New York, San Francisco and London, 1977.) $48.

Autoimmunity was considered thirty years ago as a contradiction in terms. If immunity, then regarded almost entirely to be due to antibodies, eliminated or neutralised microbes and other foreign substances which had penetrated the body it would be terribly dangerous to make antibodies against one's own tissues. Furthermore, no-one had convincingly shown that antibodies against self components were normally ever made. Antibodies could indeed be induced which reacted with an animal's own spermatozoa, lens protein or even brain tissues, but it was argued (sometimes correctly) that these were exceptions, as the antigens involved were in fact excluded from contact with cells of the immune system; and when brought into contact by infection or by injury they were essentially foreign. With improved techniques, however, undoubted autoantibodies were described in an increasing number of human diseases, such as haemolytic anaemia, thyroiditis, pernicious anaemia and rheumatoid arthritis. Autoantibodies became respectable, although it was still uncertain in most cases whether they caused the disease or were a secondary consequence of tissue damage, which had resulted in liberation of specialised tissue components that were normally hidden intracellularly but were recognised once they entered the blood stream.

The notion that autoimmunity did not occur—expressed by Ehrlich's term 'horror autotoxicus'—had been so widely accepted that few had bothered to question how the body could distinguish self from not self. In terms of current biochemical knowledge the phenomenon was inexplicable, but the clonal selection theory put forward by Burnet in 1959 made sense in terms of cell populations. It proposed that all lymphocytes potentially able to make antibodies against self antigens were eliminated if they met them during foetal life, and that auto-antibodies were the products of 'forbidden' clones, which had undergone somatic mutation after the period of obligatory development of self tolerance was over. This explanation had the added advantage of accounting for the increasing incidence of autoimmunity with age. However, in immunology few hypotheses remain intact for long. It was found that normal animals could quite easily be induced to develop autoantibodies against thyroglobulin by immunising with cross-reacting thyroglobulin, that inbred strains developed anti-thyroid antibodies spontaneously, and that normal animals contained lymphocytes with surface immunoglobulin receptors specific for thyroglobulin (and for other self components) even though they made no detectable antibodies. This implied that a considerable number of forbidden clones could not have been eliminated.

New light was shed when it was realised that specific T lymphocytes, recognising the 'carrier' part of antigens, are required to cooperate with B lymphocytes for the latter to secrete antibodies against a particular antigenic determinant. T lymphocytes are more easily inactivated by contact with antigen; the specific helper T lymphocytes having been eliminated, the B lymphocytes able to make autoantibody would only do so if an alternative set of helper cells were available. These could be provided by stimulating with cross-reacting antigens or self antigens altered in some way, such as by viral infection. Absence of autoimmunity could now be attributed to lack of helper T cells. Next came the recognition of the existence of suppressor T

Phase Transitions is the first journal devoted exclusively to this fast growing subject. It provides a focus for papers on most aspects of phase transitions in condensed matter. Although emphasis is primarily on experimental work, theoretical papers are welcome if they have some bearing on experimental results. The areas of interest include structural (ferroelectric, ferroelastic, high pressure precipitation, order-disorder, Jahn-Teller, martensitic, etc.) phase transitions, geophysical phase transitions, metal insulators, superconducting and superfluid transitions, magnetic phase transitions, critical phenomena and physical properties at phase transitions including liquid crystals, technological applications of phase transitions.

COMPREHENSIVE ORGANIC CHEMISTRY

The Synthesis and Reactions of Organic Compounds

Chairman and Deputy Chairman of the Editorial Board
SIR DEREK BARTON, FRS & W. DAVID OLLIS, FRS

Quotations from the reviews published in *Tetrahedron* 1978, Vol. 34, No 23:

LORD TODD, PRS, Cambridge, reviewing Volume I (Stereochemistry, Hydrocarbons, Halo Compounds, Oxygen Compounds; edited by J.F. Stoddart, Sheffield):

> *"I confess that I have been much impressed by Volume I, largely, of course, because it meets my criteria for a personal reference text for the practising organic chemist . . . . If the other five volumes adequately match the first then* **Comprehensive Organic Chemistry** *will fill a long-felt need and should be a success."*

G. OURISSON, Strasbourg, reviewing Volume 2 (Nitrogen Compounds, Carboxylic Acids, Phosphorus Compounds; edited by I.O. Sutherland, Liverpool):

> *"The present volume is probably typical of the complete series. It is 'medium-sized', has a very wide coverage, relies heavily on existing reviews and books, and is definitely up-to-date. . . . I am convinced that the emphasis is right; that the book, and certainly the series, will find daily use in most organic chemical laboratories, for quite a long time."*

G. STORK, New York, reviewing Volume 3 (Sulphur, Selenium, Silicon, Boron, Organometallic Compounds; edited by D. Neville Jones, Sheffield):

> *"Judging by this volume, which I take to be representative of the whole work, it is clear that every serious chemistry library will have to acquire this set . . . . Many transformations that one would like to be familiar with are now presented in convenient and completely up-to-date fashion. Comprehensive Organic Chemistry will be an all but essential companion in synthetic explorations."*

R.U. LEMIEUX, FRS, Edmonton, reviewing Volume 4 (Heterocyclic Compounds; edited by P.G. Sammes, London):

> *"This fine contribution well surveys the exceedingly complex and ramified field of heterocyclic chemistry while remaining pleasantly readable . . . It will undoubtedly find extensive use in both industrial and academic libraries. Consultants and research chemists should consider it for office usage — the retrieval in a coherent fashion of a wide range of important factual knowledge has been made reliably convenient."*

W.S. JOHNSON, Stanford, reviewing Volume 5 (Biological Compounds; edited by E. Haslam, Sheffield):

> *"To a synthetic organic chemist the chapters are not only comprehensible but interesting and highly informative . . . This is a first-class treatment of the subject . . . . Haslam and his colleagues are to be congratulated for producing such a magnificent segment of the Barton-Ollis magnum opus which indeed represents a major contribution to scholars of organic chemistry."*

J.E. BALDWIN, FRS, Oxford, is reviewing Volume 6 (Author, Formula, Subject, Reagent, Reaction Indexes; edited by C.J. Drayton, Oxford) and his review will be published shortly.

Free copies of the full text of all the reviews, together with a brochure describing the work, may be obtained from the publisher on request.

Six Volume Set (only supplied in sets). Approximately 8,000 pages
Price US$1250 £625 ISBN 0 08 021319 7

PERGAMON PRESS Headington Hill Hall, Oxford OX3 0BW, UK Fairview Park, Elmsford, New York 10523, USA

cells, which could prevent helper cells from being stimulated or from functioning. Certain strains of animal unusually prone to autoantibody formation were found to show premature loss of suppressor cell function, and the regulatory role has been shifted to suppressor cells. Instead of self-reactive cells being absent we now have to consider them as normally present, but kept in check by an elaborate feedback system. Jerne's network hypothesis, whereby any lymphocyte specifically responding to an antigen may stimulate a specific response against itself, and so on, provides a theoretical model whose usefulness is being increasingly recognised and validated.

Against this background an up-to-date book on autoimmunity was needed. The contributors to the present multi-author volume are all experts. The topics covered in 23 chapters range from genetic control of autoimmunity in man and other species (including an interesting account of the history of NZB and NZW mice); ways in which autoimmunity can come about covering examples illustrating all the various mechanisms discussed in the introductory part of this review; role of suppressor cells; relevance of the network theory; other feedback mechanisms, including blocking factors; correlation of autoimmunity with malignancy, immunodeficiency and with a variety of viral infections; special aspects of autoimmunity, including SLE, rheumatoid arthritis, diseases of the central nervous system, and antibodies against physiologically important receptors in thyrotoxicosis and myasthenia gravis; a very full account of the pathological effects of immune complexes; and a final chapter on how autoimmune (anti-idiotype) responses can be used for positive and useful regulation. The level is advanced, but the language is reasonably clear and the book should be useful for clinicians as well as professional immunologists. The coverage is not complete (for example, there is little about haemolytic syndromes, skin diseases or the gut) but the aspects covered are done well. Bibliographies are more than adequate, and there is a reasonably good index. This book is the best and most up-to-date currently available.

J. H. Humphrey is Professor of Immunology at the Royal Postgraduate Medical School, Hammersmith Hospital, London, UK.

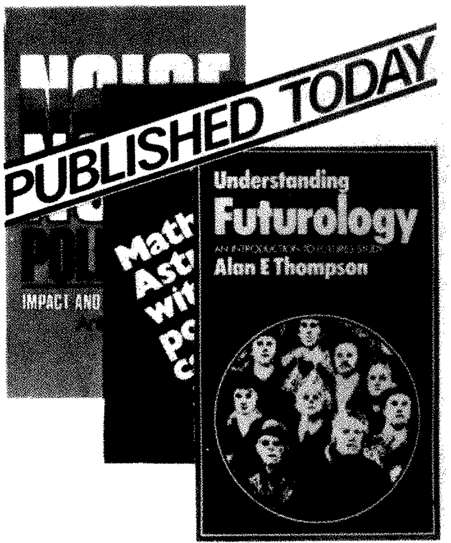
Nuclear power engineering

Nuclear Power. Vol. 1 : Nuclear Power Plant Design. Vol. 2: Nuclear Power Project Management. By Erik S. Pedersen. (Ann Arbor Science : Ann Arbor, Michigan; Wiley: Chichester, UK, 1978.) £18.60 each volume.

IN recent years nuclear engineers have undoubtedly suffered from a surfeit of excitement. After the oil shock of 1973 nuclear engineers were acclaimed as potential saviours, and almost simultaneously accused of plotting the obliteration of the planet. Nuclear engineers have seen their industry expand at breathtaking speed, only to watch now as it threatens to subside like a punctured balloon. Nuclear engineers hear politicians proclaiming the wonders and prestige of nuclear enterprise, while ducking as the groundlings throw eggs. Nuclear engineers might well welcome a little boredom. If so, may I prescribe two volumes of Erik Pedersen, taken at bedtime?

Given a topic as potentially engrossing as nuclear energy—fascinating phenomena, virtuoso engineering, daunting challenges of every kind to be met—it cannot have been easy to write 950 pages of unrelenting tedium. But both volumes of Pedersen's *Nuclear Power* read like computer printouts, an avalanche of factual information recited in a dogged monotone, in which even the most ingenious intricacy is embalmed lifeless on the page. Indeed both volumes of *Nuclear Power* read disconcertingly like each other. The first is called *Nuclear Power Plant Design*, the second *Nuclear Power Project Management;* but perhaps one-quarter of the text in the second volume is lifted verbatim from the first, without any apparent indication of this repetition. The unwary purchaser may react more emotionally to the text when he realises belatedly that he has unwittingly paid for two helpings of it.

It is not, in any case, clear just who is expected to read the books. The Preface to each volume opens with the statement that it "is intended to be used as a working reference book for management, engineers and designers, and as a graduate-level text for engineering students. The book is designed to combine theory with practical nuclear power engineering and design experience, and to give the reader an up-to-date view of the status of nuclear power and a basic understanding of how nuclear power plants function". A much better writer than Mr Pedersen would be hard pressed to find a level at which all these disparate objectives could be even minimally met. As a result both volumes of *Nuclear Power* include far too much material that



NOISE POLLUTION
Impact and Countermeasures
Antony Milne
Directly related to the economic growth of a country, noise is a modern problem approached differently in every continent but universally misunderstood or ignored. Antony Milne assesses this dangerously underestimated pollutant and offers partial solutions . . . society has to pay some price for its progress.
0 7153 7701 9 £5.95
UNDERSTANDING FUTUROLOGY
An Introduction to Futures Study
Alan E Thompson
Imagine a world in which every possible, indirect, seemingly unconnected consequence of a proposed action is evaluated . . . a world in which the progress of science and technology ceases to amaze, its accompanying problems and pollutants cease to dismay. Intelligently directed effort could lead to an improved – perhaps more human – future.
0 7153 7761 2 £4.50
MATHEMATICAL ASTRONOMY WITH A POCKET CALCULATOR
Aubrey Jones
For astronomical problems which demand accurate solutions in a minimum time, the electronic calculator once again proves itself invaluable to the modern scientist. Sidereal and mean time, reduction to apparent place, binary star orbits and planetary co-ordinates are just some of the subjects covered with fully demonstrated methods for both algebraic logic calculators and those employing Reverse Polish Notation.

Circle No. 11 on Reader Enquiry Card.

would go far over the head of the reader desiring "a basic understanding"—unexplained references to "eigenvalues" and other jargon, and some of the most hair-raising equations *ex machina* ever put to paper, with no hint of derivation or underlying assumptions—while omitting to provide essential detail which any responsible designer, engineer or manager would require before making use of much of the information in the books.

Volume 1 opens with a chapter on nuclear reactor theory, which at once undermines the reader's confidence by getting a well-known number wrong: the Trinity test took place not on 6 July but on 16 July 1945. It may be merely a typographical error, but any book with as much undefended numerical data as this cannot afford such a demoralising error on page 2. This and subsequent chapters might serve as a recapitulation for those who already know the subject and simply need to have their memory refreshed; but the explanations will require much expansion by any student using the book as a first-time text. The questions at the chapter-ends might have been drawn from the author's draft outline: "1. Explain the buildup of atomic structure. 2. Explain the atomic number and mass number. 3. What is an isotope? . . ." and so on. A student could regurgitate the foregoing text verbatim—but might not have the faintest idea of its meaning. The chapter on 'Nuclear reactor design' uses the word 'design' as a noun, not as a verb; nowhere is there any effort to discuss the actual process of nuclear design. Instead there are reams of description, naming of the parts There are chapters on 'Types of nuclear power plants' (mostly repeated in Volume 2) and licensing (ditto, and entirely taken up with US procedures), on shielding, containment, steam and turbine cycles, electricals, instrumentation, and radioactive waste management. Volume 2 also includes chapters on safety analysis, project services, quality assurance, scheduling and plant operation, nuclear fuel management and plant cost management. Appendices list terminology and US regulatory guides. Unfortunately the index is skimpy, making the books less useful even as a concise nuclear encyclopaedia.

The economic information is alarmingly erratic. "The annual fuel expense equals about $25/kWe, which, over 30 years of plant life, implies expenditures of $750/kWe for nuclear fuel": only if you buy all the fuel at the beginning, or ignore the entire process of discounting and the economic track record of the civil nuclear industry. Similar flat statements of purported economic fact could be disputed at great length. So could the declaration of faith with which the author concludes the books: "Nuclear power is the safest, cleanest and least expensive energy source available today and in the foreseeable future. We must, therefore, take advantage of it." Given the losses so far sustained by those engaged in civil nuclear power worldwide, it is not clear who is taking advantage of whom. However, it is unhappily clear that these two volumes will do little to raise the flagging esprit de corps of Mr. Pedersen's colleagues, nor entice fresh blood into the enterprise.

Walt Patterson

Walt Patterson is energy consultant to Friends of the Earth (London) Ltd.

Annelid physiology

Physiology of Annelids. Edited by P. J. Mill. Pp. 683. (Academic: New York and London, 1978.) £28; $58.

THIS book should probably be compared with the Annelid volume of Florkin and Scheer's series on Chemical Zoology, the closest thing we have had until now to a volume on annelid physiology. Happily, only 5 of the 14 chapters in Mill's volume cover topics previously reviewed, and only two of these are by the same authors (Clark on systematics and Oglesby on osmoregulation). Comparable reviews must otherwise be sought in volumes devoted to specific physiological systems (for example, respiration and reproduction); there, in fact, they may be somewhat more useful, as physiologists are more often interested primarily in their physiological specialty and less frequently interested in results in all fields of physiology from a specific group of animals.

The volume has unfortunate technical flaws (smeared print on a number of pages in my copy) and numerous distracting errors in grammar, punctuation, and figure labelling (especially in the editor's chapter) which detract from the flow of the text. These are in addition to frequent, obvious typographical errors.

Richards' chapter on the epidermis and cuticle is a welcome summary, although more might have been included on gland cell ultrastructure, and several erroneous statements on seta formation in reproductive forms of polychaetes are included. Mill provides a list of most of the information available on sense organs and their associated pathways, but offers little synthesis.

Tashiro and Kuriyama's mistitled chapter on neurosecretion is really a good review of synapses and neurotransmitters as they occur in annelids. Annelid neurosecretion in the neuroendocrine, peptidergic sense has been reviewed several times in recent years, but neurotransmitters have been somewhat neglected; thus, the chapter is more useful than the title would lead one to believe.

Olive and Clark's chapter on reproduction nicely complements the only other recent review of this subject. Division of annelid species into monotelic and polytelic groups (that is, those which breed only once and those which breed more than once) provides an interesting touchstone especially for the analysis of polychaete life cycles. It particularly illuminates the various possibilities for physiological control. Polychaete diversity is as evident in reproduction as it is in feeding habits and external structure and this classification offers an opportunity to analyse this diversity on a rational basis.

In separate chapters, Weber discusses both respiration and the respiratory pigments. His approach is functional and he provides a good summary of the abundant recent work, especially on the pigments and their function. The diversity of polychaete life styles and respiratory pigments provides interesting material for the investigation of physiological and biochemical adaptation, and enough work has now been done in this area to sketch the broad outline of different probable physiological strategies in different respiratory stress situations. Mangum provides a critical, constructive review of the related area of temperature adaptation. These chapters emphasise polychaete diversity and will doubtless command a good audience.

In an unusual chapter on defence mechanisms, Dales reviews several neglected, and somewhat disparate topics including wound-healing (a neglected component of regeneration), responses to both parasites and microorganisms, and, briefly, graft rejection and immunity.

Oglesby's exhaustive and critical review of salt and water balance physiology again emphasises polychaetes and their diversity. This chapter ought to stand for some time as the definitive statement of our knowledge in this area.

Considering the cost of a volume such as this, both the reader and the contributing authors have a right to expect better quality from both the editor and the publisher.

CANCER GENETICS AND CYTOGENETICS

Editor-in-Chief

Avery A. Sandberg. Chief of Medicine C, Roswell Park Memorial Institute, Department of Health, State of New York, 666 Elm Street, Buffalo, New York 14263

Associate Editor-in-Chief

Herman van den Berghe, Leuven, Belgium

Aims and Scope

The aim of CANCER GENETICS AND CYTOGENETICS is to publish papers of originality and high scientific quality in the various areas of genetics and cytogenetics (e.g., human, animal, molecular, population, biochemical), as they relate to the broad field of cancer, in order to reach as multidisciplinary an audience as possible.

Subscription Information

CANCER GENETICS AND CYTOGENETICS will commence publication in mid-1979. Volume 1 will consist of four issues. Subscription rates are $30.00 for individuals and $60.00 for institutions. Subscribers outside the U.S.A. should add $4.00 for surface mail, $10.00 for air delivery to Europe and Canada, and $16.00 for air delivery to the rest of the world.

Sample copies available upon request.

ENERGY AND THE ENVIRONMENT

Democratic Decision Making

Edited by J. Surrey, Christian Lenzer, C. Phipps and J. Valleix

The outcome of a lively conference at the Council for Europe in Strasbourg, this book examines the challenges facing Europe over the next quarter-century arising from the complex and interrelated problems of energy and environment policy.
The stark choice confronting politicians the report says, is between on the one hand, allowing societies to maintain present life-styles and trends and neglecting the risk of future resource scarcity, and on the other hand of preparing public opinion for unpopular decisions needed to avert future crisis.

Contents

Introduction – Energy Needs, Resources and their Conservation, 1985–2000 – Non-nuclear Energy Resources and their Environmental Impacts – The Nuclear Option: For and Against – Future Policies – The Closing Sitting and Communique....

Publication: 14th December; £5.95; 0 333 25627 1

COAL DEPOSITS
ORIGIN, EVOLUTION, AND PRESENT CHARACTERISTICS

J. H. TATSCH

This is no ordinary book on coal deposits. Nor does it simply detail the locations and gross characteristics of the Earth's coal deposits. Rather, it shows how coal deposits have originated, have evolved, and have become emplaced into their present environments in accordance with a single, long-lived, deep-seated mechanism that has been operating within the Earth during the 4.6 billion years that the Earth is believed to have been in existence, with particular attention to the Carboniferous, Permian, Cretaceous, and Tertiary periods. The mechanisism used is the "tectonospheric earth model," which has been described in the book, **THE EARTH'S TECTONOSPHERE** (1972), and used as the basis for the books, **MINERAL DEPOSITS** (1973), **PETROLEUM DEPOSITS** (1974), **GOLD DEPOSITS** (1975), **COPPER DEPOSITS** (1975), **URANIUM DEPOSITS** (1976), **GEOTHERMAL DEPOSITS** (1976) and **EARTHQUAKES** (1977).

Chapter headings: 1, The origin of coal; 2, The global distribution patterns of coal deposits; 3, The geometrical, mechanical, thermal, and chemical behaviour of the Earth during the past 4.6 billion years; 4, Plate tectonics, omniductive processes, and seismotectonomagmatic belts; 5, Precambrian seismotectonomagmatic belts and the associated coal deposits; 6, Paleozoic seismotectonomagmatic belts and the associated coal deposits; 7, Mesozoic seismotectonomagmatic belts and the associated coal deposits; 8, Cenozoic seismotectonomagmatic belts and the associated coal deposits; 9, The present distribution of coal deposits as a function of the Earth's behaviour during the past one billion years; 10, The Tectonospheric Earth Model as a supplementary tool in the exploration for coal deposits. Appendix: The Tectonospheric Earth Model: a new concept.

This book, composed almost entirely of proprietary material, summarizes the results of an independent research project undertaken to determine the most probable geometrical, mechanical, thermal, and chemical aspects of the origin, evolution, and present characteristics of the Earth's coal deposits. Because of its proprietary nature, very little of this material has been published in journals. Nor is it expected that very much of it will be offered for publication other than in book form. This approach, we feel, permits the reader to gain a better perspective of the subject matter presented.

May be ordered directly from the address shown below or from book dealers in all parts of the world. Hard cover, 6 x 9 inches, 450 pages. Table of contents, line drawings, index, maps, references. $156. ISBN: 0-912890-13-4. LC: 76-28096. 1979. (In press.)

Tatsch Associates

120 THUNDER ROAD, SUDBURY, MASSACHUSETTS 01776, U.S.A.

NOTE: A pre-publication price of $132 is effective until 28 February 1979; thereafter, the list price ($156) is effective.

NATURE

We invite applications for 1979 Writing Fellowships and Sabbaticals at *Nature*.

Writing Fellowships

There will be opportunities for two or three scientists or journalists to travel on our behalf and write feature articles and news stories based on their experiences. We see these fellowships as a means of extending the coverage of our news pages.

Sabbaticals

We shall also have two or three vacancies for scientists with a particular interest in editing or writing to spend a short period working with the *Nature* staff.

For further details and application forms please write to:

The Editor, *Nature*,
4 Little Essex Street, London WC2R 3LF

stating which scheme you are interested in.

obituary

Manne Siegbahn, 1886–1978

MANNE SIEGBAHN, who died on 24 September 1978 at the age of nearly 92, was one of the great leaders in the development of experimental atomic physics during the first half of this century. He is known in particular for his pioneering work in X-ray spectroscopy, for which he was awarded the Nobel prize in 1925, and as an eminent organiser of research in experimental physics in Sweden, where he created and led very productive research groups at Lund (1914–1923), Uppsala (1924–1937) and Stockholm (1937–1964).

Siegbahn began his academic career in 1906 at the University of Lund where J. R. Rydberg was then professor in physics. His dissertation in 1911 (on magnetic field measurements) had no connection, however, with Rydberg's famous work on series in atomic spectra, nor had it any bearing on Siegbahn's future line of research. At that time, atomic physics was in a state of rapid development. In 1913, Bohr's model of the atom, based on Rutherford's nuclear atom and the radiation laws of Planck and Einstein, had quantitatively explained the hydrogen atom, but no clear path through the jungle of amassed data on other atomic spectra was in sight.

A more promising way of getting an insight into atomic structure seemed to appear when Moseley, in 1914, by using the newly discovered Bragg reflection from crystals was able to measure the wavelengths of the X-rays emitted by different elements and found their very regular dependence on the atomic number. Siegbahn saw the possibilities of this approach and immediately put the available resources of the laboratory in Lund into the development of X-ray spectroscopy. Showing for the first time his remarkable aptitude for instrument design Siegbahn developed to perfection the crystal spectrographs and the X-ray tubes as well as the vacuum technique which was a big experimental problem in those days. He transferred his own enthusiasm to his group of students, and the laboratory in Lund became a centre for X-ray spectroscopy which attracted researchers from many countries.

As a result of a decade of hectic activity the knowledge of the X-ray spectrum of different elements was enriched with many details, the range extended toward short and long wavelengths within the limits set by the crystals, a new series (M) was discovered and the wavelength measurements were improved step by step to a high degree of precision. For practical reasons the wavelengths had to be expressed in a special (Siegbahn) unit based on an assumed value for the lattice constant of the crystals. The experimental technique was described and the observational data collected in Siegbahn's book *Spektroskopie der Röntgenstrahlen* that went through several editions, each time revised and extended, and became the bible for workers in this field.

Having been acting professor and head of the laboratory since 1915 Siegbahn was appointed to the chair in 1920 after Rydberg's death. In 1923, however, Siegbahn accepted an invitation to the chair of physics at the University of Uppsala, where he soon assembled a new group of devoted students. Although X-ray spectroscopy remained for some time the main interest, other more or less related activities were initiated. Among them was the determination of the fundamental atomic constants, leading, for example, to a considerable revision of Millikan's oil drop value for the atomic unit of electric charge.

Around this time it had been shown that X-rays could be diffracted by ruled gratings if the rays made a small enough angle with the reflecting surface (grazing incidence). Realising the possibility offered by this method to extend the observable range of X-ray spectra, Siegbahn built in 1928 a grazing-incidence concave-grating spectrograph which had the characteristic features of a Siegbahn design: it was simple, efficient and easy to work with. It proved its value and was followed by several similar instruments of increasing size. Besides amply fulfilling the hopes of extending the range of X-ray spectroscopy, these instruments effectively opened up the almost inexhaustible field of investigations into the 'optical' spectra of highly ionised atoms. The gratings used in these spectrographs were ruled on a ruling engine of Siegbahn's own design.

In 1937 Siegbahn moved to Stockholm to become director of a new research institute created for him by the Academy of Sciences with financial support from the Wallenberg foundation and the State. Established as a department of the Academy's Nobel institute it became generally known as the Nobel Institute for Physics.

Anticipating the coming importance of nuclear physics which began to develop during the first half of the 1930s, Siegbahn planned the new institute especially for research in nuclear physics which up to then had been almost completely neglected in Sweden. The institute was equipped with one of the first cyclotrons in Europe and with excellent facilities for nuclear spectroscopy. For the third time Siegbahn managed to assemble a large group of able collaborators and made the Nobel Institute a centre for nuclear research of high international reputation. Siegbahn formally retired from the directorship in 1964, at the age of 78, but continued to maintain a keen interest in the activities of the Institute.

Manne Siegbahn's success as a research leader was founded on a deep interest in the subject matter as well as a feeling for the potential fertility of a field and an unhesitating readiness to take up new lines of research. As a designer of instruments he saw the essential functional requirements and found the most direct way of solving the problems. In his contacts with people Siegbahn was a man of few words, but what he said was always to the point and his quiet manner was not to be taken as a sign of timidity. On the contrary, he possessed the large amount of contagious self-confidence needed for bold enterprises. Siegbahn took little interest in formal teaching and he gave his research students a great deal of freedom in their work, at the same time keeping them aware of his generous encouragement.

Bengt Edlén

E. A. Moelwyn-Hughes

WITH the death, on 10 September 1978, of Emyr Alun Moelwyn-Hughes, Fellow of Darwin College and for many years Lecturer in the University of Cambridge, the world of chemistry has lost one of its luminaries.

He was born in Cardigan in 1905 one of the six children of the Rev. Dr J. G. Moelwyn-Hughes, a well known Welsh Presbyterian minister and hymnologist. After a remarkable career as a student in the University of Liverpool, who awarded him a DSc at the age of 28, and where his interest in kinetics was first aroused by Prof. W. C. McC. Lewis, he went to Magdalen College, Oxford as 1851 Exhibitioner.

It was there, alongside C. N. Hinshelwood with whom he collaborated, that his work on solution chemistry and the comparison of the rates of change in the gaseous and liquid state first flourished. His interests soon encompassed ionic reactions, enzyme catalysis, the isotope effect and the general theory of solutions. The first of his classical texts *The Kinetics of Reactions in Solutions*, which greatly influenced the subsequent development of the subject, was published in 1933, at about the time when he embarked on a year's collaboration with K. F. Bonhoeffer at the Institut für physikalische Chemie, Frankfurt.

In 1934 he moved to the University of Cambridge where, apart from the war years when he was associated with the Ministry of Supply, he remained for the rest of his life, except for short visits abroad. He held the Messel Fellowship of the Royal Society from 1936 to 1940, and later became a Vice President of the Chemical Society.

As a teacher in Cambridge, and as an extraordinarily successful author of several standard texts, he influenced the careers of countless young scientists. One of his own research associates (J. C. Kendrew) became a Nobel laureate, and many others reached distinguished heights. They were taught at the time when his own experimental contribution was at its apogee: at a time when he wrote the often-quoted 'the complete physical chemist blows his own apparatus and solves his own equations.'

But he will be remembered best for his scholarly authorship of texts which were widely acclaimed. Moelwyn-Hughes wrote about his chemistry with the consummate skill of the accomplished creative artist. His dignified fluency, together with his wit, percipience and perspective, was altogether refreshing in its originality and impact. Molecules, and other inanimate entities of the physical world, were frequently endowed with human qualities; and he contemplated the beauty, magic and mystery of their behaviour in the best traditions of the natural philosopher and poet. He had the innate feeling for the right turn of phrase. On listening to him, or reading his work, one was impressed by the freshness of his metaphors, which were invariably newly minted. And he obviously relished the act of regulating the rhythm of his sentences. His physical chemistry was described with the right words in the right order. Some of the gems that constitute part of his legacy trip off the tongue: 'Energy among molecules is like money among men; the rich are few, the poor numerous.' 'Belief in the essential simplicity of things is one of the chemist's articles of faith.' And consider his discussion of the self-evident fact that the liquid state of matter is intermediate between the solid and gaseous states. 'Like a central party in politics or a moderate denomination in religion, the liquid state is less rigorously defined and more difficult to understand than either of the extremes that flank it.'

His introduction to the Everyman Edition of *The Sceptical Chemist* (1963) is a model of succinct historical exposition. In asking when the discovery of the inverse relationship between pressure and volume was made and who was Robert Boyle, he wrote: 'He flourished in the seventeenth century, that turbulent time of pestilence and fire so amply described by Evelyn and Pepys, when Bunyan wrote in Bedford jail and Penn left England's shores, when Milton sang his *Paradise Lost* and Wren built London's churches, when Britain's monarch was overthrown and Cromwell made Protector.' His book-reviews were also delightfully composed.

Moelwyn-Hughes was greatly admired by many. He was appreciated as a significant figure in twentieth century physical chemistry. His coruscating, if sometimes caustic, wit was much enjoyed (and occasionally feared) as was his superb storytelling gift; and very many including those Welshmen who got to know him at the University of Cambridge Welsh Society (Cymdeithas y Mabinogi), valued his warm-hearted friendship.

His illness was prolonged: for many years he was struck with immobility and incapacity. During that time he uttered not a syllable of complaint; and throughout it all he was nursed with profound affection and care by his devoted wife Mair who, along with his twin sons Edmwnd and Rolant, survive him.

J. M. Thomas

F. C. Fraser

DR FRANCIS CHARLES FRASER, CBE, FRS, Polar Medal 1942, a cetologist of international distinction and Keeper of the Department of Zoology at the British Museum (Natural History) from 1957 to 1964, died on 21 October 1978 at the age of 75. A graduate of Glasgow University, where his interests had been in both zoology and geology, his love of the sea and an appropriate opportunity sent him to the Antarctic and South Georgia from 1925–1933. His early work with the 'Discovery Investigations' was on the development and distribution of the young stages of *Euphausia* (*Discovery Rep.* 1936, 14, 1).

From the time of his appointment to the museum in 1933 as an Assistant Keeper, Fraser devoted his research to various aspects of cetology. He took over the *Reports on Cetacea, stranded on the British Coasts* which had been initiated in 1913 by Sir Sidney Harmer. This involved the development of communications between coastguards and other authorities and the museum, and then recovery, identification, measurement, and preparation of specimens to ensure the fullest scientific use of each stranded cetacean Successive *Reports* were published in 1934, 1946, 1953 and 1974. Each contained analyses of strandings by species, site and distribution, number per month, estimated age, time of birth and summaries of many other findings useful in building up facts about the life histories of cetaceans. Altogether (from 1913–1966) 1,550 cetaceans were identified by Harmer and Fraser. These reports have been so valuable that other countries have begun to publish similar records.

During the Second World War, Fraser worked at the Admiralty. Afterwards he joined the 'Atlantide' expedition (1945–1946) and studied cetaceans off the coasts of West Africa. He soon confirmed his reputation as a leading cetologist, especially on the often difficult decisions of identification: people from all parts of the world came for his help. His numerous taxonomical notes, mostly on rarer species, provided clarification where there was usually utter confusion.

In 1956 he described a species of dolphin *Lagenodelphis hosei* from a single skeleton collected before 1895 on a beach in Sarawak. From 1971 onwards sightings and captures have been made in widely scattered parts of the world to 're-discover' what is now known as Fraser's dolphin

He contributed original observations on the anatomy, especially cranial osteology, and morphology of many cetacean species and made use of stranded animals brought to the museum both for research and display. The Whale Hall's present existence and its popularity owe much to Fraser's desire to educate the public about whales and dolphins He also supported many of the early enterprises to exhibit live dolphins. His informative museum guides to British cetaceans and his splendid book with J R. Norman, *Giant Fishes, Whales and Dolphins* are meticulously accurate

A substantial work was that with P. E. Purves on Hearing in Cetaceans (*Bull. Brit. Mus* (*Nat. Hist.*) *Zool* 1960, 7, 1) This dealt with anatomical and experimental evidence to demonstrate that hearing was by way of the external auditory meatus, it was precisely discriminative and directional and the cetacean ear was sensitive to a wide range of frequencies. The elaborate sinus system was shown to be an extension of the middle ear cavity and could be a guide to the systematic arrangement of the Order Cetacea.

Fraser had a deep interest in the history of cetology and wrote about Peter Mundy's 'Greenwich Whale of 1568, early Japanese whaling, William Scoresby Junior and on the Grey Whale in Icelandic waters. His last contribution (1977) was on 'Royal Fishes: The Importance of the Dolphin'. This paper contained a lifetime's research and reflection on the Royal Prerogative in Britain which he had traced back as far as the 13th century.

Fraser was proud of his Dingwall stock and delighted in being a pawky Scot of the dry, humorous kind; yet there was nothing but solicitude and generosity about him, consideration for anyone deserving of it and an unrelenting determination to see justice done. It could well have been of him that Herman Melville wrote: 'But I have swam through libraries and sailed through oceans, I have had to do with whales with these visible hands; I am in earnest; and I will try.'

R. J. Harrison

A. S. McFarlane

ARTHUR SPROUL McFARLANE, Head of the Biophysics Division at the National Institute for Medical Research from 1945 to 1970 died on 4 October 1978.

He was born in Glasgow on 18 April 1905. He took 1st class honours in biochemistry at Glasgow University in 1928, and qualified in medicine in 1931. From 1931–33 he was biochemist at the Glasgow Royal Cancer Hospital, and was elected to a Beit Memorial Fellowship in 1933 to work in Uppsala under Professor The Svedberg on the use of the recently developed oil-turbine ultracentrifuge. The studies which he made of a wide range of serum proteins illustrated the potential of this new technique for the characterisation of normal and pathological proteins in mixtures.

When the Rockefeller Foundation, anxious to make the instrument available to other laboratories, offered one to the Lister Institute, McFarlane joined the Institute to continue his Beit Fellowship and to supervise the installation of the Svedberg machine in a specially constructed building. The installation was completed in 1937, by which time he had become a member of the Lister Institute staff and had been joined by R. A. Kekwick. They also acquired the newly developed Tiselius electrophoresis apparatus—both instruments being the first of their kind in the UK—and in 1938 published the first paper arising from their use on the "Physical properties of bushy stunt virus" recently crystallised by F C. Bawden and N. W. Pirie.

Further work on vaccinia virus was interrupted by the war, when his attention changed to devising a means for preparing stable human plasma for transfusion. He invented a novel means of removing unstable lipids by freezing below −25 °C with ether, and went on to design large scale freeze drying plant. This was done at the L.C.C. Serum Institute, Carshalton, where the laboratory had been transferred in 1941.

In 1943 McFarlane's services were requested by the National Institute for Medical Research to supervise the design and installation of special services, including one of the early electron microscopes, in the new building at Mill Hill (built in 1938 but used meanwhile by units of the Women's Royal Naval Service and finally occupied in 1950).

When in 1945 the US Atomic Energy Commission announced that radioisotopes produced in uranium chain-reactors would be available for peaceful uses to scientists all over the world, McFarlane was sent by the Medical Research Council to negotiate the supply of radioisotopes for the UK. Hopes were rudely shattered by the passage in 1946 of the McMahon Act forbidding exportation from the US of all radioactive materials produced in atomic piles, but McFarlane through his friendship with Robley Evans, in charge of the cyclotron at the Massachussetts Institute of Technology, managed to obtain sufficient ^{32}P to allow research workers here to get the feel of radioisotopes and experience in design of counting instruments.

In 1947 he was again sent to the US and to Canada to negotiate purchase of other radioisotopes and this mission was entirely successful. (A fuller account appears in an article by Professor George Popjak in *Trends in Biochemical Sciences*, October 1976.)

By the time that the N.I.M.R. finally moved to Mill Hill in 1950 McFarlane had been responsible for making it the best equipped medical research laboratory in England in respect of biophysical instrumentation. By designing an elaborate but efficient apparatus for counting ^{14}C after combustion to ^{14}CO$_2$ and installing a mass spectrometer he also gave his colleagues a headstart in the use of the radioactive and stable isotopes then available.

His own interests became concentrated on studying the metabolism of plasma proteins, using ^{14}C and radioiodine as trace labels. He devised a method for labelling proteins with radioiodine, which avoided denaturation and by studies on antibodies in collaboration with J. H. Humphrey showed that biological activity and ^{14}C internal and ^{131}I external labels were catabolised at identical rates. This validated radioiodine labelling and led to a series of definitive measurements on the turnover of several plasma proteins in normal and sick subjects, in which McFarlane collaborated with workers in Britain, the USA and elsewhere. He also developed an ingenious method for measuring plasma protein synthesis *in vivo* involving simultaneous measurement of incorporation of ^{14}C from labelled urea and ^{14}C from bicarbonate.

By temperament he was a shrewd Scotsman, with what might nowadays be considered an old fashioned outlook on life, but certainly capable of enjoying it. He was at his best when devising apparatus or techniques, and would have made his mark in industry had he chosen this career. Although his own approach to biological problems was simple (sometimes over-simple) and mathematical, he greatly helped many biological colleagues by providing them with technological back-up at a time when the array of sophisticated equipment nowadays provided by scientific instrument manufacturers was not available.

J. H. Humphrey

newly on the market

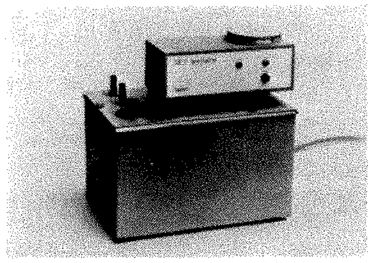
Nitrate electrode. Electronic Instruments. A nitrate electrode has been added to the range of ion-selective electrodes of Electronic Instruments. Model 8006-2 is of the capsule design ensuring easy assembly and minimal maintenance. The new ion exchanger used gives improved selectivity for NO$_3$ in the presence of Cl$^-$, an important breakthrough in nitrate determinations in sewage and industrial effluents.
Circle No. 47 on Reader Enquiry Card.

Nuclear magnetic resonance spectrometer. Perkin-Elmer. Perkin-Elmer announces the model R-600 high-resolution, Fourier Transform NMR spectrometer. A high stability permanent magnet provides a 14,092 gauss field for proton observation at 60 MHz. Combined with an easy-to-use microcomputer data system to control instrument functions, the R-600 offers users the capability of obtaining NMR spectra, in a routine manner, on quantities of 500 mg or less, at half the cost of existing Fourier Transform instruments. High resolution spectra over long-term accumulation are possible with the model R-600 through the use of an internal deuterium field/frequency lock that provides a field stability within a few tenths of a Hertz. System resolution is 0.5 Hz. Integration accuracy is 2.5% (5% ethyl benzene).
Circle No. 48 on Reader Enquiry Card.

Regulator. Tescom. Tescom 44-2200 series regulators are designed to prevent contamination of high purity systems and provide accurate regulation of any corrosive or noncorrosive gas or liquid. For corrostive applications, all media wetted parts are type 316 stainless steel or Du Pont Teflon. High purity systems are further protected from contamination through metal-to-metal sealing of diaphragm between body and bonnet. Soft seals are not used. Models are available for primary pressures of 3,000 p.s.i.g. and 400 p.s.i.g. with choice of secondary pressure ranges of 0–25 p.s.i.g., 0–50 p.s.i.g. and 0–100 p.s.i.g. Gauge ports standard on cylinder regulators.
Circle No. 46 on Reader Enquiry Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the cover.

Constant temperature circulator. Techne. In response to the frequent need in the laboratory for a small low-cost compact constant temperature circulator, Techne has introduced the Model SP670 open tank circulator. This unit was developed specifically to provide a controlled temperature of 55 °C in the reaction column of a solid phase peptide sequencer. However, the unit will also find general use in the laboratory. The model SP-670 uses the TE-7 solid state immersion circulator with 500 W heater fitted to a small deep drawn tank and with inlet and outlet pipes for connection to a closed circuit external system. The bath is fitted with a top up port. Temperature range is 0–95 °C and control obtainable is ±0.02 °C.
Circle No. 45 on Reader Enquiry Card.



The TE-7 immersion circulator

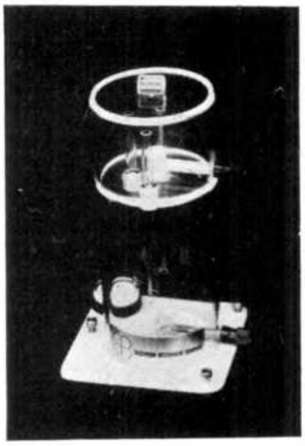
Four-channel non-fade scope. British American Optical. The model 1144, a four-channel non-fade scope, provides monitoring of ECG, arterial pressure, plus third and fourth parameters on a large, bright, moving trace display. Internal selections permit adaptation of the display format to many different monitoring situations. Circuitry includes four dynamic shift register memories each with 1,024 word capacity, delayed outputs being coded to facilitate distinguishing between real time and delayed signals, and between those that were previously frozen and those that were not.
Circle No. 44 on Reader Enquiry Card.

Effluent quantity and quality meter. Philips. A new portable flow meter from Philips can carry out the accurate measurement of waste water flow rates automatically, even in the presence of surface foam, scum or floating objects. The PW 9816 meter uses a dipping probe to sense the level of water in a measuring channel of known cross section, giving a direct correlation with the rate of flow. Attached to a weighted flexible cable mounted on a rotating drum, the probe is raised and lowered at regular intervals. Contact with the water surface completes an electrical circuit. The resultant signal is electronically converted and used to drive a pen that produces a trace on a circular chart. The PW 9816 can be used in conjunction with a wide range of standard wiers, flumes and venturis, and produces a record of flow rates in m^3 min^{-1} and, via a computing integrator, total flow since the start of measurement.
Circle No. 42 on Reader Enquiry Card.

IBM—compatible terminal system. Control Data announce the first of a series of multiple-function computer terminals that can be operated as stand-alone processors to terminal devices by business users of IBM 360 and 370 computer systems. The unit, called the Control Data C760 multifunction terminal, can be programmed by non-technical operators. The clerical operator can generate and execute application programs on the terminal using a simple forms language that is provided with the basic terminal system. The CDC C760 terminal is available in a minimum configuration that includes a microprocessor-controlled keyboard and visual display terminal.
Circle No. 43 on Reader Enquiry Card.

Environmental monitor. Research Products International. Now available from Research Products International Corporation is a portable G-M tube environmental monitor, Model 6-70. Supplied with a special compensated MC-70 type G-M tube, this instrument is designed for determining environmental γ radiation levels. The highly sensitive detector is suitable for measuring low intensity radiation within a reasonable time period. Sensitivity is approximately 150 pulses s^{-1} for a 1 μR h^{-1} exposure rate. Measurement over a period of 1,000 s will give a result having a statistical accuracy of ±3% for a background of 7 μR h^{-1}. The Model 6-70 is designed for field use and is powered by Ni-Cd rechargeable batteries giving 10 h run per charge. A tripod stand is available allowing the detector to be located 10 m away from the instrument.
Circle No. 50 on Reader Enquiry Card.

Tube gel electrophoresis apparatus. Dickinson. This three-sample, tube gel electrophoresis apparatus from Dickinson is designed for quick tests of molecular weight range, restriction enzyme activity, buffers, ampholytes and gradients. The model TG-3 accommodates all types of gel techniques including polyacrylamide, agarose and isoelectric focusing. Up to three, 5 mm diameter tube gels with a length between 4 cm and 15 cm can be run simultaneously. The apparatus has clear acrylic plastic construction and platinum wire electrodes.
Circle No. 51 on Reader Enquiry Card.



The Dickinson model TG-3

Emission spectrometer. Philips. Modular construction and the availability of a wide range of sample excitation options make the new PV 2850 emission spectrometer from Philips an adaptable system for fast, simultaneous multi-element analysis of solids and liquids. This compact air-path spectrometer operates automatically and can be used to determine up to 60 elements simultaneously. A choice of modular electronics can be incorporated, while various computer hardware/software packages are available for instrument control and output of results as element concentrations.
Circle No. 52 on Reader Enquiry Card.

Cold light illumination system. Specfield. A fibre optic cold light illumination system, the SLS 75 light source with double-branched flex-and-stay fibre bundle, has been announced by Specfield. Primarily designed for microscope illumination and as a cold-light source for close-up photography of small heat-sensitive subjects, the SLS 75 houses a 75-W fan-cooled quartz iodine lamp. The light from the lamp is concentrated onto the end of a double-branched fibre-optic light guide which is securely held in the front panel of the unit. The unit operates on 240 V a.c., and a 110 V a.c. version is available.
Circle No. 53 on Reader Enquiry Card.

Pressure filtration apparatus. Millipore. Millipore's Teflon pressure filtration apparatus is made entirely of non-metallic surfaces and is designed for field or laboratory use in sampling all types of waters where there is a requirement to separate particulate from dissolved heavy metals fractions. Certified filters of specified metallic ion content are used to retain the particulate fraction. These can then be totally digested in suitable acid cocktails for subsequent amino acid or other instrumental analysis to determine and differentiate particulate from dissolved heavy metals. Filtering of 500 ml–6 l of potable and highly turbid waters is effected in a matter of minutes.
Circle No. 54 on Reader Enquiry Card.

Gel scanner. ISCO. The ISCO model 3010 gel scanner will produce both UV scans on unstained gels and visible scans on stained gels. UV scanning of a cylindrical gel in its original quartz running tube simplifies determination of the minimum time required for the maximum revolutions and provides accurate quantitation of each peak. The unit consists of the ISCO absorbance chromatography monitor, model UA5 and the gel transporter unit, thereby offering an instrument for performing two functions in the protein laboratory.
Circle No. 55 on Reader Enquiry Card.

Medical linear accelerator. Varian. The Clinac 20 from Varian is a highly versatile dual-modality medical linear accelerator that offers great flexibility in treating malignant tumours, and can selectively generate either a 15 MV X-ray (photon) beam or an electron beam variable over 6–20 MeV. The Clinac 20 has an output of up to 500 rads per min with treatment field sizes that range from 0×0 to 35×35 cm at the 100-cm isocentre. The extra high output means treatment can be given to patients in less time than is now required with lower radiotherapy machines.
Circle No. 56 on Reader Enquiry Card.

Electrophoresis power supply. Buchler. The model 3-1500 constant power supply from Buchler Instruments offers researchers the convenience of a bright digital display of output with the exacting performance required for such procedures as electrofocusing. Push-button controls select the appropriate output ranges and regulation mode. Constant voltage, constant current and constant power may be selected at levels up to 1,000 V d.c. 200 mA and 200 W. A fault circuit prevents any damage from occurring to the unit in cases of external shorts or open circuits.
Circle No. 57 on Reader Enquiry Card.

Digital thermometer. Channel Electronics. Designed for bench or rack mounted applications, the 7500 series of mains powered digital thermometers have been introduced by Channel Electronics. Nine basic units are available, with thermocouple and platinum resistance inputs, and together they offer a temperature measurement capability from −220 °C up to 1,750 °C, to a resolution of either 0.1 °C or 1.0 °C. Thermocouple units incorporate an improved cold junction compensation system for greater stability and reliability. The gas discharge display provides a clearly discernible read-out at a range of up to 40 ft. Options include a fully linearised voltage output and non-standard calibrations are available for all linear or non-linear millivolt, milliamp or resistance inputs.
Circle No. 58 on Reader Enquiry Card.

Laboratory titrators. Electronic Instruments Limited. A major expansion of the EIL laboratory product range has taken place with the launch of a comprehensive series of automatic laboratory titrators. The range, consisting of Karl Fischer, endpoint, *ph* stat and recording titrators, all incorporate a unique photoelectric counting device, which ensures that titrant and samples are dispensed with the highest possible precision.
Circle No. 59 on Reader Enquiry Card.

EIL Laboratory titrators

Stereoscopic microscopes. Olympus. The Series VM of stereoscopic microscopes from Olympus consists of two basic models, VMT and VMF. The VMT is a turret magnification change type with ×1 and ×2 or ×1 and ×4. The VMF is a fixed magnification model with choice of ×1, ×2 or ×4. All versions share a common range of auxiliary lenses, eyepieces, stands and accessories. Special attention has been paid to the lighting available with the series and the stand has been designed to accept a minimum of 11 different methods of illumination. A very special feature is the base illuminator which offers transmitted, epi' or combined illumination.
Circle No. 60 on Reader Enquiry Card.

UNIVERSITY OF ASTON IN BIRMINGHAM

DEPARTMENT OF BIOLOGICAL SCIENCES

FISH NUTRITIONIST

Applications are invited for a Lectureship in Biological Sciences. The successful candidate will be expected to contribute to the teaching of general nutrition and metabolic biology within the Department. Candidates must have research interests in fish nutrition, preferably in the field of vegetable and single cell protein utilisation

Commencing salary will be within the range £3,883 to £5,842 per annum on a scale rising by annual increments to £7,754 per annum (under review).

Application forms and further particulars may be obtained from the Staff Officer (Ref. No 331/6) University of Aston in Birmingham, Gosta Green, Birmingham B4 7ET (Tel 021 359 3611, Ext 201) to whom applications should be forwarded not later than February 23, 1979

9287(A)

UNIVERSITY COLLEGE LONDON

LECTURER IN CHEMISTRY

Applications are invited for a Lectureship in the Department of Chemistry from October 1, 1979 Candidates should have special interests in organic chemistry or in biological chemistry or in both It is expected that the appointment will be made within the lower part of the lecturer salary range, the whole of which is £3,909 to £7,754 plus £450 London Allowance.

Further particulars can be obtained from the Assistant Secretary (Personnel), University College London, Gower St, London WC1E 6BT, and applications (6 copies if possible) should reach him on or before March 16, 1979

9330(A)

MEDICAL RESEARCH COUNCIL

National Institute for Medical Research

IMMUNOLOGIST

A young postdoctoral immunologist is required by the LABORATORY FOR LEPROSY AND MYCOBACTERIAL RESEARCH to investigate immunity of mycobacterial infections. It is proposed that the person appointed will study particularly the immunological control of the growth of mycobacteria in tissue culture and in animals

The appointment will be for up to three years and will be in the salary range £4,408 to £6,080 per annum according to age and qualifications, plus £450 p a. London Allowance Superannuation provision

Applications, giving details of qualifications, experience and the names of two professional referees, should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA, before March 31, 1979.

9334(A)

EXPERIENCED RESEARCH ASSISTANT

required for a one-year project in human metabolism. Work involves amino acid analyses and metabolite assays as part of an investigation of parenteral nutrition.

Salary c.a £3,930 depending on qualifications and experience.

Apply in writing to Dr B. D Ross, Department of Clinical Biochemistry, Radcliffe Infirmary, Oxford. 9307(A)

DIRECTOR DALTON RESEARCH CENTER UNIVERSITY OF MISSOURI COLUMBIA

This multidisciplinary facility for basic biological research, graduate and postgraduate training is supported principally from state funds, as well as from Federal agencies and foundations. A new building of 60,000 sq ft in Research Park, adjacent to the main campus, has excellent research laboratories with modern animal shop, computer, controlled environment, and other facilities

A Director is sought with commitment to outstanding research who will develop a dynamic research unit in a life science area. The Director will be expected to bridge and complement Dalton Center activities with selected existing talents and resources on the UMC campus, examples are cardiovascular regulation, cellular and developmental biology, molecular genetics, immunobiology, neurosciences, and bioenginering.

This is intended as a "Center of Excellence" and the University is committed to providing a competitive Director's salary and other resources to insure success. The Director should have research management experience, including budgeting, recruiting, and generating research funds.

The Director will be tenured in an academic department of UMC The University is a Land Grant school with a student enrollment of 23,000 On a single campus, it has a unique combination of life science-oriented Divisions (Medicine and other health related sciences, Agriculture, Veterinary Medicine, Engineering, and Biological Sciences) Particular research strengths may be found in departments of Biochemistry, Physiology, Biological Sciences, Bioengineering, Medicine, Microbiology, Pharmacology, Radiology, and Surgery University resources include Reactor Research Center, Cancer Research Center, Health Services Research Center, Veterans Administration Hospital, University of Missouri Medical Center, and Eye Research Institute

Women and members of minority groups are urged to apply Résumés and other appropriate information should be sent to:

Search Committee for Director
Dalton Research Center
Research Park
University of Missouri
Columbia, Missouri 65211

Closing date: March 10, 1979.

The University of Missouri is an Equal Opportunity Employer

9335(A)

APPOINTMENTS VACANT

CHAIRPERSON

BIOCHEMISTRY DEPARTMENT

THE UNIVERSITY OF MASSACHUSETTS MEDICAL SCHOOL

is seeking an individual who has a proven commitment to excellence in research and has demonstrated expertise in teaching and administration to chair its Department of Biochemistry The Department presently has strength in the areas of cyclic nucleotides, hormonal control of metabolism and nutrition. Several faculty positions will become vacant by September of 1979 and may be filled by the new chairperson. The successful candidate will be expected to lead a department that is both exceptional in its research and committed to quality teaching of biochemistry to medical and graduate students

Please send curriculum vitae, bibliography and three references by March 15, 1979 to: Dr F. S Fay, Chairman, Search Committee, Department of Physiology, University of Massachusetts Medical School, 55 Lake Avenue North, Worcester, MA 01605.

Minority and women candidates are encouraged to apply The University of Massachusetts is an equal opportunity/affirmative action employer

9339(A)

THE UNIVERSITY OF LEEDS

PROCTER DEPARTMENT OF FOOD SCIENCE

RESEARCH FOR SCHOOL SCIENCE MASTERS

Applications are invited from graduate Science Masters in Schools to take part in research in the Procter Department of Food Science for a period of four weeks in the summer vacation. Two places are available in 1979 and grants to cover expenses incurred are available from the Worshipful Company of Skinners through its Lawrence Atwell's Charity. The research will be of a chemical or physical nature and topics will be selected with subsequent continuation in school laboratories in mind either as part of the school science syllabus or as a research project. The scheme is subject to an age limit of 29.

Applications, giving details of career and interests, and the names of two referees, should be sent as soon as possible to the Head of the Department, Proctor Department of Food Science, University of Leeds, Leeds LS2 9JT.

9297(A)

WESTMINSTER MEDICAL SCHOOL DEPARTMENT OF THERAPEUTICS

requires a

Research Assistant

to join an active research team, including medical staff of Westminster Hospital, who are studying the clinical pharmacology of drugs used in the chemotherapy of cancer.

Candidates should be graduates in chemistry or a biological discipline. They should also have a sound practical knowledge of the techniques of drug analysis, including G.L.C. and H.P.L.C., coupled with some research experience. The successful applicant will also participate in the on-going departmental research programme relating to molecular mechanisms of drug action.

Salary, according to age and qualifications, will be in the range £3,834 to £5,332, inclusive of London Weighting (review pending).

Applications, with names and addresses of two referees, to Dr B. A. Brooks, Department of Therapeutics, Westminster Hospital, London SW1P 2AP. Tel: (01) 828-9811 ext. 2490.

9316(A)

Science v. Crime

Opportunities for graduates in Advanced Forensic Investigation.

In the fight against crime science is an increasingly active agent in uncovering facts from subtle but often decisive evidence in cases such as murder, rape, arson and burglary. Science can successfully answer the critical questions—"who?", "when?", "where?", "how?"—which provide the police and the courts with invaluable assistance in the maintenance of law and order and the administration of justice.

The Forensic Scientists in the Home Office have access to advanced analytical techniques which bring to light new sources of evidence. The forensic laboratories at Aldermaston, Birmingham, Bristol, Cardiff, Chorley, Nottingham and Wetherby (the laboratories at Bristol and Cardiff will move to Chepstow in 1979) are being comprehensively equipped with sophisticated instrumentation for use in gas and high pressure liquid chromatography, mass spectrometry, scanning electron microscopy, electron microprobe analysis, radio immuno assay, atomic absorption spectrophotometry, X-ray fluorescence spectroscopy and other methods.

Work in the Forensic Science Service offers graduates opportunities for advanced scientific investigation associated directly with criminal investigation—often involving visits to the scene of the crime and giving evidence at court.

There are openings for honours graduates (including those qualifying in 1979) in chemistry, biochemistry, biology, pharmacy, physics, materials science and related scientific disciplines, and encouragement will be given to obtain further qualifications. Appointment as Scientific Officer (£2,840 to £4,410) or Higher Scientific Officer (£4,100 to £5,450), according to qualifications and experience. Good colour vision is essential.

For further details and an application form (to be returned by February 19, 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours).

Please quote ref: SY/22/LA/2.

9347(A)

UNIVERSITY OF WALES

UNIVERSITY COLLEGE OF SWANSEA

SENIOR RESEARCH ASSISTANT

Applications are invited from physicists/electrical engineers with experience in Computing, or from mathematicians/computer scientists, with an interest in the application of numerical methods to physical situations, for the vacancy of **Senior Research Assistant in the Department of Physics.** The successful applicant will work on an S.R.C. sponsored project to simulate numerically the electrical breakdown of a gaseous dielectric.

The appointment which will be for two years from the soonest date that can be arranged, will be on a scale up to £4,382 per annum plus U.S.S./U.S.D.P.S. benefits.

Further particulars and application forms (two copies) may be obtained from the Personnel Officer, University College of Swansea, Singleton Park, Swansea SA2 8PP, to whom they should be returned by Friday, February 9, 1979.

9301(A)

GLASGOW COLLEGE OF TECHNOLOGY

The Glasgow College of Technology, a major polytechnic institution of higher education, invites applications for the following post:

RESEARCH ASSISTANT in OPHTHALMIC OPTICS

The successful applicant would be required to work on an agreed topic in Ophthalmic Optics. Applicants should hold appropriate qualifications in Ophthalmic Optics, or alternatively an honours degree in a discipline such as Physics, physiology or psychology, and should have a strong interest in visual problems. The person appointed will be expected to read for a higher degree of the CNAA, Master or Doctor of Philosophy.

Salary: The Research Assistant will be paid 50 per cent of the appropriate point on the Lecturer 'A' scale: £4,029 to £7,110 Bar-£7,638. Placing on the salary scale will be according to relevant experience.

Application forms and further particulars can be obtained from the Establishments Officer, Cowcaddens Road, Glasgow G4 0BA.

Application forms should be returned not later than Friday, February 2, 1979.

Edward Miller, Director of Education, Strathclyde Regional Council.

9267(A)

THE LONDON HOSPITAL MEDICAL COLLEGE
(University of London)

RESEARCH ASSISTANT
IN BONE AND JOINT UNIT

Applications are invited for the post of Research Assistant in the Bone and Joint Unit. The post will be tenable for approximately 2½ years.

The project with which the successful applicant will be associated concerns development and evaluation of methods of detecting autoantibodies in human disease.

Candidates should have an I.M.L.S. qualification or appropriate practical experience in medical laboratory work.

Salary: £3,384 to £4,882 plus £450 London Allowance per annum, together with superannuation under the U.S.S.

Enquiries to Professor E. J. Holborow. Telephone: 01-247 8939.

Applications to the Secretary, The London Hospital Medical College, Turner Street, London E1 2AD, enclosing curriculum vitae and names of two references.

9300(A)

POSTDOCTORAL POSITION

open for chemist/biochemist/crystallographer interested in protein and nucleic acid crystallisation.

Starting March 1: DM1,900 per month tax free.

Send C.V. and list of publications to Prof. Dr W. Saenger, Max-Planck-Institut für experimentelle Medizin, Hermann-Rein-Str. 3, 3400 Göttingen, **W.-Germany.**

9299(A)

MEDICAL RESEARCH COUNCIL
DUNN NUTRITION UNIT

Postdoctoral research worker required to undertake studies on energy balance in man. Studies will be conducted in a new metabolic suite incorporating three whole body calorimeters at the Unit's Clinical Nutrition Centre, Addenbrooke's Hospital, Cambridge. Experience in human physiology desirable, with or without a medical qualification. The appointment is for three to five years, with salary according to qualifications.

Further details and applications by February 15, 1979, to Dr W. P. T. James, Dunn Clinical Nutrition Centre, Addenbrooke's Hospital, Trumpington Street, Cambridge CB2 1QE.

9186(A)

COMMUNITY ECOLOGIST

The University of Kansas anticipates a 12-month tenure-track position as Assistant Professor, Division of Biological Sciences, and Assistant Curator, Museum of Natural History (joint appointment) available July 1, 1979. Community Ecologist with theoretical emphasis; experience with vertebrate communities and their vegetational bases. Duties curatorial and teaching, including research and graduate student guidance. Ph.D. required prior to assumption of duties. Send curriculum vitae, reprints, and direct three letters of reference to: Frank B. Cross, Museum of Natural History, University of Kansas, Lawrence, KS 66045, by March 15, 1979. Salary range $17,000 to $19,000. Equal Opportunity/Affirmative Action Employer.

9284(A)

UNIVERSITY OF LONDON
ROYAL POSTGRADUATE MEDICAL SCHOOL
SAFETY OFFICER

Applications are invited for this newly established post, the holder of which will be Secretary of the Safety Committee and will be responsible to the School Secretary for the implementation of safety policy.

Applicants should have a sound knowledge of safety matters. Particular knowledge of safety considerations in laboratories would be an advantage, but is not essential.

Salary on grade II for academic-related Administrative Staff: £6,317 to £7,754 (under review) plus £450 a year London Allowance.

Superannuation under Universities Superannuation Scheme.

Further particulars should be obtained from the Secretary, Royal Postgraduate Medical School, Hammersmith Hospital, Du Cane Road, London W12 0HS (tel. no: 01-743 2030 ext 352), to whom applications (6 copies) should be sent, naming three professional referees, to arrive not later than Wednesday, February 28, 1979. 9253(A)

CHELSEA COLLEGE
(University of London)
BASIC MEDICAL SCIENCES GROUP

There is a vacancy in the Physiology Department for a

RESEARCH AND TEACHING TECHNICIAN (Grade 4)

with an interest in practical electronics applied to electrophysiological problems We should be pleased to hear from suitably qualified or experienced and interested persons who should, in the first instance, contact Susan Holly, Department of Physiology, Chelsea College, Manresa Road, London, SW3 6LX (01-352 6421) for further details and application forms

The salary scale for this post is £3,420 to £3,867 per annum (under review), including £465 London Allowance. 9252(A)

UNIVERSITY OF LONDON
INSTITUTE OF PSYCHIATRY
RESEARCH WORKER
(Scale 1A)

required for a investigation of factors controlling the enzymic methylation of tryptamines in animal and human tissues. Supported by MRC grant

Salary in range £3,384 to £4,382 per annum plus £450 London Allowance. Application forms and further details available from The Secretary, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF quoting reference RR/N Application forms should be returned by February 23, 1979 9251(A)

ROYAL POSTGRADUATE MEDICAL SCHOOL
DEPARTMENT OF CLINICAL PHARMACOLOGY
SCIENTIFIC OFFICER

equired to work on a number of reearch projects, centred on hypertenion The projects will include radiodgand binding studies of receptors, rostacyclin pharmacology and catebolamine turnover The candidate hould possess a degree or equivalent n a related subject Experience in eneral biochemical techniques is required and a working knowledge of at east one of the projects is desired

Salary on scale £3,887 to £6,169 a ear, starting salary dependent on exerience.

Application form and further partiulars may be obtained from the Peronnel Office, Royal Postgraduate edical School, 150 Du Cane Road, ondon W12 0HS quoting reference umber 20/103/N 9250(A)

---

unilever research

Ice Cream Research Assistant

Our Ice Cream and Dairy Section has a vacancy for a Research Assistant.

Tasks:

The job will involve:

(i) obtaining physical test data on ice cream and relating this to sensory properties, formulation etc;
(ii) the organization of the running of the ice cream mini-line;
(iii) work on development of new products generally in connection with Unilever companies.

It will also involve organising the work pattern of an assistant and trying to develop a detailed understanding of the structure and important consumer attributes of ice cream. The job will require an appreciation of the different requirements for ice creams in various countries and an ability to identify and analyse problems with equipment under the supervision of the job holder.

Qualifications:

Candidates of either sex, should have a sound scientific background. He or she should have an interest in the measurement of both sensory and instrumental properties of foods as well as an interest in food processing and product development. The position would be suitable for a graduate with a physical sciences degree and little or no experience although experience of ice cream would be an advantage.

Colworth Laboratory

The Colworth Laboratory is located in a very attractive 1200 acre country estate ten miles north of Bedford. Salaries and fringe benefits are at a level expected of a large international company and includes assistance with moving expenses where appropriate.

Please write quoting reference CH-491A and giving details of career history to:

Miss J. Kenny,
Recruitment and Career Development Manager,
Unilever Research,
Colworth Laboratory,
Unilever UK
Central Resources Ltd.,
Colworth House, Sharnbrook,
Bedford, MK44 1LQ.

9315(A)

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL
RESEARCH MEDICAL LABORATORY SCIENTIFIC OFFICER

required for three years to join a clinically based research team led by Professor A N Exton-Smith, Barlow Professor of Geriatric Medicine, studying the Immunology of Dementia

Starting salary £3,582 and London Weighting on incremental scale

The work will involve the application of immunological techniques to samples from normal and demented aged people. Preference will be given to candidates with some experience in laboratory immunology

Applications and enquires to Dr R Callard, Human Immunology Laboratory, University College Hospital Medical School Tel. 01-387 9300, ext 199 University Street, London WC1 9342(A)

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL
(University of London)
DEPARTMENT OF GASTROENTEROLOGY
GRADUATE OR RESEARCH TECHNICIAN

Applications are invited for the above post to develop new methods of pancreatic function A sound practical knowledge of biochemistry is essential and experience in radioimmunoassay though not essential would be desirable. The post is for 2 years in the first instance and the salary, within the range £3,261 to £4,680 (plus London Weighting).

For further details please telephone Dr P R Salmon, 01-388 2411, ext 241. Applications giving details to The Secretary, University College Hospital Medical School, University Street, LONDON WC1E 6JJ, quoting Reference RT/Ga 9343(A)

UNIVERSITY OF LONDON
Institute of Psychiatry
DEPARTMENT OF NEUROPATHOLOGY
JUNIOR TECHNICIAN

required to work on project involving research on biochemical causes of brain damage Basic knowledge of methods of biochemical analysis, especially of amino acids, desirable and an interest in electronics an advantage Applications from recent school leavers with 'A' level Chemistry would also be considered.

Whitley Council Terms and Conditions for Medical Laboratory Junior Scientific Officers A or B. Starting salary in range £2,259 to £3,243 per annum (including London Weighting) depending on age and qualifications. The post is grant-supported for three years.

For application form, please write to the Assistant Secretary, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF or Telephone 703 5411, Ext 214, quoting reference OEP/N. 9291(A)

Wellcome

Biochemist/Molecular Biologist

£5,000 – £9,000

Department of Immunochemistry

A postdoctoral scientist with proven experience in techniques leading to the identification, isolation and characterisation of specific DNA sequences is required to join an enthusiastic young group pursuing the study of cell surface antigens. It is anticipated that the person appointed will be anxious to involve others in the application of DNA technology to the identified research objectives.

Candidates should have a relaxed attitude to collaboration and the motivation and ability to make a significant contribution to a basic research programme with the long-term objectives of better understanding, diagnosis and prevention of disease.

Starting salary will be in the range £5,000-£9,000 per annum and will be dependent on age and experience.

The Laboratories are situated in pleasant parkland surroundings within easy reach of Central London and conditions of employment are excellent and include subsidised canteen, pension scheme, 4 weeks' holiday, relocation expenses where appropriate and sports and social facilities.

For an application form, please write to the

Personnel Manager,
The Wellcome Research Laboratories,
Langley Court, Beckenham, Kent BR3 3BS.

9326(A)

REGIONAL CYTOGENETICS LABORATORY, EAST BIRMINGHAM HOSPITAL

BASIC GRADE SCIENTIFIC OFFICER

Applications are invited for the new post of Scientific Officer. Experience in cytogenetics desirable but not essential Salary range depending on experience and qualifications—£2,991 to £4,899 per annum.

Application forms and job descriptions obtainable from Regional Cytogenetics Laboratory, East Birmingham Hospital, Bordesley Green East, Birmingham B9 5ST Tel. No. 021-772 4311, Ext. 4354. 9318(A)

UNIVERSITY OF GLASGOW

SECOND CHAIR OF ZOOLOGY

The University invites applications for a second chair in its Department of Zoology.

Further particulars may be obtained from the Secretary of the University Court, (Room 18), University of Glasgow, Glasgow G12 8QQ, with whom applications (15 copies, 1 copy in the case of overseas applicants), giving the names and addresses of three referees, should be lodged on or before March 16, 1979

In reply please quote Ref. No. 4270M 9317(A)

THE UNIVERSITY OF HULL

DEPARTMENT OF PLANT BIOLOGY

GRADE 6 TECHNICIAN

Applications are invited for the post of Technician in charge of the teaching services in the Department of Plant Biology. Candidates should hold an H.N.C. or equivalent qualification and have 9 to 10 years experience. The post is tenable from mid-April Salary on the scale £3,654 to £4,365 (under review).

Applications, giving details of age, qualifications, experience and the names of two referees should reach the Personnel Officer, University of Hull HU6 7RX, by February 9, 1979 Further particulars are available

9324(A)

MEDICAL RESEARCH COUNCIL

PNEUMOCONIOSIS UNIT

Llandough Hospital, Penarth, South Glamorgan CF6 1XW

Young graduate or equivalent required to work on the development of new physical methods for quantifying asbestos fibres in human tissues and in the air Some experience of instrumentation would be helpful.

Starting salary dependent on age and experience but probably within the range £3,261 to £3,582.

Application forms obtainable from the Assistant Administrative Officer at the above address. 9322(A)

UNIVERSITY OF TORONTO

Physiology/Biochemistry

Applications are invited for two research appointments in the general area of gastrointestinal physiology, anaerobiasis and carbohydrate/protein intermediary metabolism

(a) Professional Associate Appropriate doctorate and postdoctoral experience required Initial appointment up to 5 years, renewable. Salary scale floor $16,000.

(b) Postdoctoral Fellow Two-year appointment Initial Salary in range $11,000 to $12,000.

Applications and the names of two referees to:

Professor D. F Mettrick,
Chairman,
Department of Zoology,
University of Toronto,
Toronto, M5S 1A1, Canada.

9327(A)

UNIVERSITY OF LEICESTER

DEPARTMENT OF GEOLOGY

LECTURESHIP IN PALAEONTOLOGY

Applications are invited for the post of Lecturer in Palaeontology in the Department of Geology.

Salary according to qualifications and experience on the scale £3,883 to £7,754 a year (under review) with superannuation benefits.

Further particulars from the Registrar to whom application should be sent by February 15, 1979. 9311(A)

UNIVERSITY OF QUEENSLAND

Australia

CHAIR OF MEDICAL BIOCHEMISTRY

The University invites applications for the Chair of Medical Biochemistry to replace Professor Chev Kidson who has accepted the position of Director of the Queensland Institute of Medical Research. Applicants should have a medical degree acceptable for registration within Queensland, and an appropriate higher degree or higher clinical qualifications. They should present evidence of achievement in biochemical research, and should have substantial teaching experience. Applications will be considered from distinguished medical biochemists who do not have medical qualifications but such applicants would be required to present evidence of significant clinical involvement in previous employment.

The successful applicant will play an important role in the development of innovative courses in basic and applied biochemistry for medical students.

The present salary for a Professor is $A33,061 per annum, plus a clinical loading, in the case of a medically qualified appointee, of up to $A5,000 per annum. The University provides prescribed travelling and removal expenses, superannuation, study leave (under review) and housing assistance. Applications close on **April 30, 1979.**

SENIOR TUTOR IN PHYSIOLOGY

Applicants should have an Honours, Masters or equivalent degree preferably in Physiology and will be expected to assist in organising practical classes in this subject and to take part in the Departmental research Programme. This currently includes work on endocrinology, renal or reproductive physiology, fetal or developmental physiology. Closing date February 10, 1979. Salary· $A13,606 to $A15,586 Other Benefits: Superannuation, Housing Assistance, travelling and removal expenses.

Additional information and application forms for both posts are obtainable from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF. 9292(A)

UNIVERSITY OF SHEFFIELD

DEPARTMENT OF PAEDIATRICS

Applications are invited for the post of TECHNICIAN (Grade 3) to assist with investigations into the physiology of somatomedins and the hormonal control of foetal growth. The work will involve the incubation of animal tissues and applicants should possess qualifications in the biological sciences Salary on scale £2,688 to £3,060 per annum (under review) Applications together with a curriculum vitae and the names of two referees should be sent to Dr D. J Hill, Department of Paediatrics, the Children's Hospital, Sheffield S10 2TH. 9319(A)

TWO POSTDOCTORAL POSITIONS

Study of nucleoskeleton from cultured animal cells and its role in the supramolecular structure of the nucleus and metaphase chromosomes Experience with DNA, chromatin, etc. desirable Study of structure and biosynthesis of cell surface heparan sulfate and possible involvement in cell interactions and with cytoskeleton. Experience in carbohydrate biochemistry preferred. Ph D in Biochemistry, Cell Biology, or allied field $12,000 plus per year Send résumé and two recommendation letters to John M. Keller, Ph D., Department of Biochemistry, University of Health Sciences/The Chicago Medical School, 2020 West Ogden Avenue, Chicago, IL 60612. Affirmative Action/Equal Opportunity Employer. 9328(A)

Institute of Cancer Research—Laboratories at Sutton, Surrey. RESEARCH BIOLOGIST required to join laboratory group investigating biology of human leukaemia; laboratory experience in tissue culture essential. The appointment is for a three year period initially. Salary according to experience in range £3,261 to £4,690 per annum. Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting ref. 301/B/54.
9256(A)

UNIVERSITY OF KEELE
Second Chair in Department of Biological Sciences

Applications are invited for the new post of Professor in the Department of Biological Sciences tenable from October 1, 1979. Applicants may be from any biological discipline except biochemistry. Salary in professorial range plus membership of F S S U / U S.S. Further particulars and application forms from the Registrar, The University, Keele, Staffs. ST5 5BG, to whom completed applications should be sent by February 28, 1979.
9271(A)

LECTURER IN ORGANIC CHEMISTRY
DEPARTMENT OF CHEMISTRY
UNIVERSITY OF SOUTHAMPTON

Applications are invited for the post of Lecturer in Organic Chemistry from October, 1979. Salary scale £3,883 to £7,754 per annum The initial salary will depend on qualifications and experience

Applications should include a curriculum vitae (seven copies), summary of research interests and names of two professional referees and should be sent as soon as possible and not later than February 28, 1979 to Mrs E. C. P. Sears, Staffing Section, The University, Highfield, Southampton SO9 5NH, from whom further particulars can be obtained. Please quote reference number 1606/R/Na
9272(A)

UNIVERSITY OF EXETER

A vacancy has arisen in the Department of Biological Sciences for a

TECHNICIAN
(Grade 3)

to work in the Electron Microscope Suite.

Applications are invited from persons with O.N C Sciences or equivalent qualifications and normally three years' experience

Salary £2,688 to £3,060 (under review)

Applications giving details of age, qualifications and experience, and naming two referees should be sent to Miss D. Watson, Northcote House, University of Exeter, EX4 4QJ by February 8, 1979 Please quote reference No. 5109.
9273(A)

BIOLOGY TEACHING OVERSEAS

Research-Teaching positions available beginning Fall 1979 in such specialties as Ecology, Plant Physiology, Developmental Biology, Invertebrate Zoology. Ph D required, rank and salary depend on experience and qualifications Usual contract is for three years with R T travel and other fringe benefits Curriculum vitae and letters of recommendation should be airmailed to Dr Samir Deeb, Biology Department, American University of Beirut, Beirut, Lebanon Application review will begin March 1, 1979
9276(A)

Computer Board For Universities And Research Councils

Joint Network Team
Appointment of Head

Recognising that flexible and compatible interconnection arrangements will play an important role in extending access to computing resources and expanding the range of facilities available to computer users in the academic community, the Computer Board and Research Councils are to set up a Joint Network Team. Its main aim will be to prepare, supervise and participate in a coordinated programme for the further development of computer networking among universities and Research Council institutes.

The specialist team is expected to consist of up to six posts and will be located at the Rutherford Laboratory, Chilton, Oxfordshire.

The responsibilities of the Head of the team will include presenting a programme of work to the Computer Board and the Research Councils for financial approval and supervising its execution. He will be called on to make recommendations to the sponsoring bodies on network plans for individual universities and Research Council institutes and to advise on technical and financial aspects of computer networking. An important part of the post will be to establish and maintain collaborative relationships with senior managerial and technical staff in computer centres throughout the academic community.

Applications are now invited from people with an interest in computer networking and with experience of university and Research Council computing. Applicants should have the ability to manage technical projects and a sound basic knowledge of computing and telecommunications technologies. Familiarity with current trends towards networking standards and proposed public packet-switched services would be an advantage.

The appointment will be for a fixed term of three years.

The salary will be in the range £10,746-£12,091 or £10,043-£11,300 depending on the superannuation scheme chosen.

Further details and an application form may be obtained from Jane Griffiths in the Personnel Group, Rutherford Laboratory. Please quote reference VN.760. Closing date for applications 12th February 1979.

Rutherford Laboratory, Chilton, Didcot, Oxfordshire OX11 0QX.
Tel: Abingdon 21900.
9337(A)

SUNDERLAND POLYTECHNIC
FACULTY OF SCIENCE
DEPARTMENT OF BIOLOGY
LECTURER II IN MICROBIOLOGY

Applicants should preferably have a first degree in Microbiology and specialism in Microbial Physiology. Bacterial taxonomists or microbial ecologists with a strong physiological background may also be considered.

Salary Scale: Lecturer II £4,101 to £6,051 Bar to £6,558.

An application form and further details may be obtained from the Personnel Officer, Sunderland Polytechnic, Chester Road, Sunderland SR1 3SD, and should be returned as soon as possible.
9270(A)

PRINCETON UNIVERSITY

The Department of Biology has an opening at the level of

LECTURER

beginning in September 1979, to teach a laboratory course in experimental vertebrate biology which is complementary to an existing lecture course Areas of interest covered by the course include vertebrate reproductive biology with emphasis on neuroendocrine mechanisms Ample opportunity will be available to carry out individual research projects, preferably in the area of vertebrate reproductive biology, including neuroendocrinology. Ph D. degree or equivalent required.

Submit letter of application, curriculum vitae, and the names of three referees to Dr R D Lisk, Department of Biology, Princeton University, Princeton, N J 08540

Princeton University is an Equal Opportunity/Affirmative Action Employer.
9280(A)

UNIVERSITY OF ABERDEEN
DEPARTMENT OF FORESTRY
RESEARCH ASSISTANT

Applications are invited for the above post to work with Dr J A Petty on an investigation of the permeability to water of wood cell wall material in relation to both water transport in the living tree and industrial wood preservation Candidates should possess a good honours degree or a higher degree in biophysics, botany, chemistry, physics or wood science

The post is tenable for three years and is supported by the Leverhulme Trust Fund

Salary £3,384 to £4,882 per annum on Research and Analogous Staff Range 1B Scale, with appropriate placing

Further particulars from The Secretary, The University, Aberdeen with whom applications (2 copies) should be lodged by February 16, 1979
9264(A)

Australian Institute of Marine Science

Laboratory Manager

Applications are invited for the above position at the Australian Institute of Marine Science near Townsville in North Queensland. Facilities completed in 1977 include a 12 8 million dollar headquarters and comprehensively equipped laboratory complex, library, lecture theatre, controlled environment rooms and aquaria, accommodation for visiting scientists and various field and technical support facilities such as deepwater boat harbour, recompression chamber and maritime service building. The research fleet includes the 24.4m RV "Lady Basten" and various smaller craft

Research at AIMS pays comprehensive attention to an understanding of the physics, chemistry and biology of the marine environment with present emphasis on tropical systems

Duties:

To be responsible for the co-ordination of laboratory requirements, for instrument maintenance and liaison with research and workshop staff in laboratory services In particular to accept responsibility for the establishment and continuing management of an analytical services facility, extending to instrumentation employed in data collection at sea.

Qualifications:

A diploma or degree in chemistry with extensive experience in analytical instrumentation and procedures combined with skills in administration and personnel interactions relevant to the duties described. Experience relevant to physical and chemical oceanography would be an advantage

Salary:

A salary commensurate with the responsibilities of the position will be negotiated

Applications:

Applications must include full c v , plus the names and addresses of three professional referees and should be sent to:

The Secretary,
Australian Institute of Marine Science,
PMB No. 3,
Townsville M.S.O. Qld. 4810.

Closing date for applications is 28 February 1979. 9288(A)

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL

(University of London)

Denmark Hill, London SE5 8RX

CHEMIST *or* BIOCHEMIST

required for exciting work on extraction and identification of lipids from mammalian tissues. Postdoctoral or equivalent experience essential Salary up to £5,579 per annum, two-year initially.

Please contact Professor Alan Bennett by telephone (01-274 6222, extension 2443) or write to Department of Surgery, King's College Hospital Medical School, Denmark Hill, London SE5 8RX 9305(A)

DEPARTMENT OF DERMATOLOGY

RESEARCH ASSISTANT/ MEDICAL LABORATORY SCIENTIFIC OFFICER

required to work in the field of cytotoxic drugs to treat cancer and other skin diseases.

Some laboratory experience necessary Salary in the range £3,261 to £4,680 plus £354 London Weighting Allowance, according to age, qualifications and experience

For further information, please contact Dr A W du Vivier on 01-274 6222, extension 2521

Apply in writing, giving full curriculum vitae and the names and addresses of two referees to the Secretary of the Medical School at the above address. 9303(A)

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF EXPERIMENTAL PSYCHOLOGY

Applications are invited for the office of

UNIVERSITY DEMONSTRATOR

IN THE DEPARTMENT OF EXPERIMENTAL PSYCHOLOGY

An interest in developmental aspects of Psychology will be an advantage but candidates with interests in other fields will be considered.

The initial appointment will be for three years from May 1, 1979, or as soon as possible thereafter The pensionable stipend for a University Demonstrator will be on a scale of £4,133 rising by four annual increments to £5,129, with initial placing above the minimum where appropriate The maximum tenure of a University Demonstratorship is five years A grant is made towards removal expenses

Candidates should send twelve copies of their application, together with the names of not more than three referees, to Mr G R Anderson, General Board Office, The Old Schools, Cambridge CB2 1TT, from whom further information can be obtained to arrive not later than March 15, 1979

9262(A)

Qualified Laboratory Scientific Officer required in Physiology Department, to assist with teaching laboratory duties and research. Salary not less than £3,261 on scale rising to £4,680, plus £354 London Weighting Apply in writing to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. P.Y.1. 9254(A)

ROYAL ALEXANDRA HOSPITAL FOR CHILDREN

Camperdown, N.S.W. Australia

BIOCHEMIST

Applications are invited for the new position of Biochemist (Principal Scientific Officer) within the Department of Biochemistry in the Hospital's Institute of Pathology.

The Hospital is a 400 bed Paediatric Teaching Hospital of the University of Sydney and offers a comprehensive range of clinical and laboratory services

The new appointee will assist the present Biochemist (Dr L Webster) in the routine work of the Department and will have special responsibilities in the development of new tests and techniques in the area of clinical paediatric chemistry. He/she will closely liaise with the Hospital's clinical staff and participate in the training programme of clinical and laboratory staff.

Applicants should hold a Ph D degree in Biochemistry or its equivalent; previous experience in clinical chemistry would be an advantage

Salary range $A21,049 to $A26,145 per annum

Further information is available from Dr R K Oates, Director of Medical Services

Applications including the names of two referees should be addressed to the undersigned as soon as possible

J. S. Yu, General Superintendent

SCIENTIST—HORMONES

We require a postdoctoral scientist with a good honours degree in medicine, physiology, biochemistry or related discipline, to work in the Division concerned with endocrinology. The work involves research into the physiology and mechanisms of action of polypeptide hormones, development of methods to measure, characterise and control them, and setting up international (WHO) standards for their bioassay and immunoassay.

There are good opportunities for collaboration, both locally and internationally.

The appointment is for 5 years in the first instance. Salary is in the range £4,359 to £7,005 per annum on M.R.C. scales, depending on age and experience.

Please write or telephone for an application form quoting reference 0187 to the Personnel Officer, The National Institute for Biological Standards and Control, Holly Hill, Hampstead, London NW3 6RB. Tel: 01-435 2232, ext. 211.

Applications should be returned not later than February 9, 1979.

9346(A)

UNIVERSITY OF THE WITWATERSRAND

Johannesburg

DEPARTMENT OF PHYSIOLOGY

Applications are invited from suitably qualified persons for appointment to the posts of:

(a) RESEARCH OFFICER/ JUNIOR RESEARCH OFFICER

Applicants for the post of Research Officer should have a medical or veterinary degree, or a Ph.D. in biochemistry, physiology, pharmacology, zoology, or any other biological field.

Applicants for the post of Junior Research Officer must have a B.Sc. or B.Sc. Honours degree in the above fields.

The successful applicants for both posts will be involved in an ongoing programme of research, at a biochemical, pharmacological, and physiological level, of cardiovascular physiology in health and disease. The Cardiovascular Research Unit is housed in a well-equipped modern cardiovascular laboratory, and current interests include work on the autonomic physiology and pharmacology of coronary artery disease and cerebrovascular disease, and the biochemical characterisation of adrenergic receptors.

(b) TECHNICIANS

Three technical posts in the Department of Physiology are vacant. One post is allocated for general Departmental duties, another for work in the University/M.R.C. Cardiovascular Research Unit, and the third in the Neurophysiology / Pain / Temperature Regulation Research Laboratory. Candidates should have a Diploma in Medical Technology, with some research laboratory experience, or should have at least a B.Sc. degree with a major in biochemistry, or any other field of biology.

The salary for the Research Officer for 1979 is up to R10,000 per annum and for the Junior Research Officer up to R7,500 per annum. Salaries for technical staff will depend on qualifications and experience.

The University's policy is not to discriminate in the appointment of staff or the selection of students on the grounds of sex, race, religion or colour. Further particulars relating to this practice are included in an information sheet obtainable from the London Representative, University of the Witwatersrand, Chichester House, 278 High Holborn, London WC1V 7HE, or from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, 2001 South Africa, with whom applications should be lodged by February 16, 1979.

9304(A)

MEDICAL RESEARCH COUNCIL

LABORATORY ANIMALS CENTRE

NUTRITIONIST

Scientists with postdoctoral research experience in the nutrition of laboratory animals, farm livestock or poultry are invited to apply for the post of head of the Centre's Nutrition department. The successful applicant will be the focus for all aspects of the Centre's work in this field and will undertake research into the nutritional requirements of laboratory animals leading to general improvements in nutrition with particular emphasis on breding performance and the lowering of mortality rates. He or she will also provide a comprehensive advisory service to diet manufacturers and users of laboratory animals.

Excellent conditions of service, attracting a salary commensurate with age, qualifications and relevant experience.

Applications, enclosing a full curriculum vitae, should reach the Director, Laboratory Animals Centre, Medical Research Council Laboratories, Woodmansterne Road, Carshalton, Surrey SM5 4EF, by March 1, 1979.

9344(A)

UNIVERSITY OF LONDON

INSTITUTE OF PSYCHIATRY

RESEARCH ASSISTANT

Applications are invited from recent graduates in biochemistry, pharmacology or a related discipline, to undertake a behavioural and biochemical investigation of the long-term effects of neuroleptic administration to rodents.

The position, which is supported by the Medical Research Council, is tenable for one year in the first instance, and may be renewed for up to three years.

Salary £3,384 to £3,883 per annum plus London Weighting.

Applicants may visit the Department (Department of Neurology) (Professor Marsden and Dr Jenner) by prior arrangement. Phone 01-703 5411, Extension 245.

Application forms available from The Secretary, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF. Phone 01-703 5411, Extension 228, quoting Ref: CM/N2.

9302(A)

MICROBIOLOGY FACULTY MEMBERS

The University of Kentucky College of Medicine has two faculty openings in the newly reorganised Department of Medical Microbiology and Immunology which are to be filled at the Assistant and Assistant or Associate Professor levels. Candidates should have a Ph.D. or M.D. and postdoctoral and/or faculty research experience. Senior-position candidates must have an ongoing funded research programme. Candidates are desired in the areas of microbial physiology, molecular genetics, molecular basis of microbial pathogenesis and gene regulation. Emphasis will be placed upon genetic, biochemical and molecular approaches to basic problems. Duties will include the development of a strong research programme, graduate student training and teaching of medical students. The positions will be available beginning approximately January 1980.

Send completed curriculum vitae including the names of at least three references to: S. Kaplan, Department of Medical Microbiology and Immunology, University of Kentucky College of Medicine, A. B. Chandler Medical Center, MN-524 Medical Center, Lexington, Kentucky 40536.

The University of Kentucky is an equal opportunity employer F/M.

9281(A)

Fibre Technology

G. D. Searle is a leading pharmaceutical company with its main U.K. site and research laboratories at High Wycombe in Buckinghamshire.

Within the laboratories we are involved in a growing number of long-term research and development programmes in various fields of medical science.

The following staff are required to develop new biocompatible materials for medical applications starting with a naturally occurring polysaccharide.

Polymer Chemist

Required to extract and chemically modify the naturally occurring polymers and to investigate alternative solvent systems. We are seeking a person with at least two years research experience working with polymers who possess a good honours degree and preferably a PH.D.

Fibre Scientist

Required to produce fibres using the wet and dry spinning techniques and to convert the fibres into knitted and woven products. Ideally we are looking for a person with proven research ability as applied to the commercial production of fibres and/or woven materials.

In addition to competitive salaries, conditions of employment include 4 weeks holiday per year, a contributory pension fund, subsidised private health insurance, sports and social club and staff cafeteria.

Applicants, male and female, should apply to Mr G. Jenkins, Personnel Manager, R & D Division, G. D. Searle & Co. Ltd., Lane End Road, High Wycombe, Bucks. (Tel. High Wycombe 21124 ext. 3374.) 9341(A)

SEARLE

POSTDOCTORAL RESEARCH ASSOCIATE

to participate in studies concerning processing of RNA and low molecular weight RNAs (gene organisation and regulation) in mammalian cells. These studies will involve cloning of DNA and sequencing, as well as other biochemical, physiological and genetic studies.

Position will be available from March 1, 1979.

Send curriculum vitae and names of three references to Dr David Apirion, Department of Microbiology and Immunology, Box 8093, Washington University School of Medicine, St Louis, Missouri 63110. Equal Opportunity and Affirmative Action Employer. M/F H.

9285(A)

TECHNICIAN/ RESEARCH OFFICER

required to assist in our Biological Safety Laboratory and the Cell Culture Laboratory. Microbiological training is essential. H.N.C. or Degree required. Salary range £3,600 to £5,200 inclusive London Weighting, pension scheme. For further information and application form, telephone Miss S. M. Hurley, Imperial Cancer Research Fund, Lincoln's Inn Fields, WC2 on 242 0200, ext. 305.

9265(A)

UNIVERSITY OF SHEFFIELD

TECHNICIAN (GRADE 3)

required for the Department of Biochemistry. The person appointed will assist in research under Professor P. M. Harrison on the structure and function of the iron-storage protein ferritin. The work includes the isolation and analysis of protein ferritin from animal tissues by biochemical techniques and assistance in the X-ray crystallographic analysis of ferritin structure (molecular model building, drawing of maps, computation, photography). Assistance in the preparation of some laboratory classes is also expected.

Minimum qualifications: O.N.C. in Applied Biology and/or Chemistry.

Salary on scale £2,688 to £3,060 per annum (under review).

Please write to the Administrative Officer (Personnel) (Ref. S1145/N). The University, Sheffield S10 2TN.

9320(A)

GRADUATE RESEARCH ASSISTANT required for work in Tissue Culture and Cytogenetics Laboratory. Experience in cell culture, cytogenetics or microbiology would be an advantage. Applications to be sent to the Administrative Assistant, Paediatric Research Unit, The Prince Philip Research Laboratories, Guy's Tower, London Bridge SE1 9RT.

9295(A)

CSIRO AUSTRALIA

Research Scientist

Division of Fisheries & Oceanography Perth, WA

CSIRO has a broad charter for research into primary and secondary industry areas The Organization has approximately 7000 employees—2400 of whom are research and professional scientists—located in Divisions and Sections throughout Australia

Field: Biological Oceanography

General: The Division is Australia's principal marine research institution with about 70 scientists investigating the physical, chemical and biological features including fisheries of the oceans around Australia Headquarters of the Division are at Cronulla, Sydney, with regional laboratories in Perth, Brisbane and a field laboratory at Karumba On-line access to a Cyber 76 computer is available. Two well-equipped medium sized chartered vessels are available for oceanographical research and there are several smaller CSIRO vessels.

Duties: To initiate and carry out research in primary and secondary productivity of limestone reefs off S W Australia, with particular attention to the interaction between offshore and onshore influences as determinants of the stability of the benthic ecosystem

Qualifications: A marine ecologist is required with experience in plant and animal physiological and biochemical ecology, and knowledge of biochemical techniques, and the use of radioactive isotopes Minimum formal qualifications are a PhD or equivalent.

Salary: Research Scientist: $A14829—$A18177 p a or Senior Research Scientist $A18819—$A21543 p.a.

Tenure: Indefinite with Superannuation

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 320/608 should reach—

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 24th February 1979.

Applications in U S.A and Canada should be sent to—The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W , Washington, D.C , 20036, U S.A. 9289(A)

INSTITUTE OF GEOLOGICAL SCIENCES

GEOCHRONOLOGIST

The Institute has a vacancy based in London for a geochronologist to undertake geological age determination studies in the U K and overseas, and to further the development of geochronology and isotope geochemistry by research into analytical methods and the interpretation of analytical data It is anticipated that work on material from overseas will constitute a major part of the activities of the post and will involve short periods of field work in developing countries Work overseas will involve co-operation with Geological Surveys and with I.G S manned technical assistance project.

QUALIFICATIONS

Applicants should normally be under 32 and have a good honours degree in geology or the physical sciences with post graduate experience in at least two methods of geological age determination work. Grade of appointment and starting salary will depend on qualifications and experience.

SALARY

Scientific Officer	£2,839 to £4,415
Higher Scientific Officer	£4,101 to £5,448
Senior Scientific Officer .	£5,154 to £6,898

Starting salary may be above the minimum. The post attracts Inner London Weighting Allowance of £465 per annum Non-contributory pension scheme.

The staff of Council are not Civil Servants but their pay and conditions of service are similar to those of scientists in the Civil Service.

For an application form to be returned by February 23, 1979, write to Establishments (Recruitment) Section, Institute of Geological Sciences, Exhibition Road, London SW7 2DE.

Please quote reference SO/IG/79/1.

NATURAL ENVIRONMENT RESEARCH COUNCIL 9306(A)

AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for appointment to the following

JOHN CURTIN SCHOOL OF MEDICAL RESEARCH

DEPARTMENT OF CLINICAL SCIENCE

RESEARCH FELLOWS

(2 positions)

Candidates for these positions should be graduates in medicine or science with appropriate postgraduate training The Department is currently undertaking biochemical and pharmacological studies on membrane function in relation to human disease Emphasis is on calcium, cyclic nucleotide and prostaglandin metabolism, asthma, diseases of muscle, malignant hyperpyrexia, platelet function, atherosclerosis, thrombosis and haemostasis, osteogenesis imperfecta, clinical pharmacology and clinical immunology

Appointment will normally be for two years but in exceptional circumstances may be for three years and extended to a total period of five years. It is hoped that the successful candidates will be able to take up their appointments in the first half of 1979.

Applicants should arrange for reports from three academic referees to be sent to the Registrar of the University in support of their applications

A salary loading of up to $A5,000 per annum may be paid to an applicant holding appropriate medical qualifications.

Further information may be obtained from the Acting Head of the Department, Dr M. A Denborough, in the University

CLOSING DATE· **February 28, 1979.**

DEPARTMENT OF IMMUNOLOGY

SENIOR RESEARCH FELLOWS/RESEARCH FELLOWS

Two positions are available for suitably qualified scientists The Department is doing research into the genetic basis of disease resistance in livestock, the major histocompatibility complex of cattle, the immunological aspect of reproduction, foetal-maternal interactions, the physiology of the immune response, transplantation biology, the immunobiology of cancer, and immunological tolerance Scientists doing research into any of these areas either from the physiological, biochemical or cellular standpoints will be considered

A salary loading of up to $A5,000 per annum may be paid to an applicant holding appropriate medical qualifications.

CLOSING DATE **February 28, 1979.**

SALARIES· Salary on appointment will be in accordance with qualifications and experience within the ranges Senior Research Fellow $A22,049 to $26,301, Research Fellow $A15,786 to $20,606 per annum Current exchange rates $A1=58p=$US1 14

Tenure: Appointment as Senior Research Fellow is normally for 3 years in the first instance with the possibility of extension to 5 years unless otherwise stated.

Other conditions: Reasonable appointment expenses are paid

Superannuation benefits are available for applicants who are eligible to contribute Assistance with finding accommodation is provided for an appointee from outside Canberra

The University reserves the right not to make an appointment or to make an appointment by invitation at any time

Prospective applicants should obtain further particulars from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. 9313(A)

UNIVERSITY OF BATH

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for an

EXPERIMENTAL OFFICER

supported by the Science Research Council to work on the structure and immunology of mammalian cell membranes with particular reference to the glycoprotein components The milk fat globule membrane is being used as a convenient large scale source of mammalian membrane and its immunochemical characterisation is currently underway.

The tenure of the post is one year Experience in gas chromatographic analysis of carbohydrates and/or immunochemistry would be an advantage, but is not essential.

Salary range £2,688 to £3,402 per annum (under review)

Application forms and further particulars from the Personnel Officer, University of Bath, Bath BA2 7AY, quoting reference number 79/10/N Closing date will be February 2, 1979 9259(A)

PRINCETON UNIVERSITY

The Department of Biology has an opening at the level of

LECTURER

beginning in September 1979, to supervise a laboratory course in introductory biology Opportunity is available to carry out independent research, depending on the qualifications of the candidate. Submit letter of application, curriculum vitae, and the names of three referees to Prof Edward C. Cox, Department of Biology, Princeton University, Princeton, N J 08540

Princeton University is an Equal Opportunity/Affirmative Action Employer 9308(A)

CENTRAL PUBLIC HEALTH LABORATORY

National Collection of Type Cultures (N C.T.C.)

SYSTEMS DESIGNER/PROGRAMMER

A systems designer/programmer, preferably a science graduate, is required for the operation of a bacterial identification service. Bacteria from clinical sources are identified by probabilistic analysis of test results by reference to computer-stored data bases Systems use Optical Mark Reader forms, Data Recognition (Dataterm 3) Machine, Extel punch tape terminal connected to the LUCS 6500 time sharing system current software in FORTRAN IV There is considerable scope for improving the responsiveness of the system and the efficient storage and retrieval of data, and to revise the methodology or explore alternative methods Sympathetic consideration would be given for specialised training, if required

Grading dependant upon basic qualifications in appropriate subjects and on experience

Salary scales. Scientific Probationary scale £2,991 to £4,275 plus London Weighting (£354); Post Probationary scale £3,798 to £4,899 plus London Weighting or Senior Scientific scale, if applicable, £5,451 to £6,837 plus London Weighting N H.S. Designated scale 9 £4,959 to £6,025 plus London Weighting

Ring 01-205 7041 for a more detailed job description (Dr L. R. Hill, on Extn. 47) and for an application form (Personnel Officer, on Extn. 12)—Central Public Health Laboratory, Collindale Avenue, Collindale, London, N.W.9 Closing date: February 15, 1979. 9293(A)

THE UNIVERSITY OF MANITOBA

invites applications and nominations for the position of

DEAN OF THE FACULTY OF SCIENCE

The Faculty of Science at The University of Manitoba has a complement of 180 faculty and 90 support staff. Its twelve departments and units span the Biological, Mathematical and Physical Sciences; they offer a full range of undergraduate Science programmes for approximately 2,100 students enrolled in the Faculty, courses for a large number of students from other faculties and schools and M.Sc. and Ph.D. programmes for about 280 graduate students.

Candidates should have achieved distinction as scholars in a major field of Science, have a commitment to advancing higher education in Science and have strong leadership ability. Relevant administrative experience and knowledge of the Canadian educational system would be assets.

The appointment is expected to commence September 1, 1979, and will be for a renewable term of normally five to seven years.

Please address responses to:

Provost R. A. Johnson,
Chairman,
Selection Committee for Dean of the Faculty of Science,
Room 202, Administration Building,
The University of Manitoba,
Winnipeg, Manitoba,
Canada, R3T 2N2.

Applications, nominations and suggestions will be received until March 15, 1979. 9171(A)

ROYAL DENTAL HOSPITAL OF LONDON SCHOOL OF DENTAL SURGERY

(University of London)

32 Leicester Square, London WC2H 7LJ

Applications are invited for the post of Lecturer in Dental Materials Science in the Department of Physical Sciences of the School The appointment will be to the permanent academic staff of the School and the successful candidate will participate fully in all aspects of the work of the Department, including undergraduate and postgraduate teaching and research, for which adequate facilities are available Applicants should have good academic qualifications and research experience in materials science or a related field.

Salary will be within the range £3,906-£7,764, plus London Allowance of £450 per annum, superannuable The successful candidate will be expected to take up duty as soon as possible Applications with full curriculum vitae and names of three referees should be submitted to the School Secretary not later than 16 FEBRUARY 1979. 9314(A)

POSTDOCTORAL POSITIONS PREDOCTORAL POSITIONS

The University of Kentucky College of Medicine has both postdoctoral and predoctoral positions available within the Department of Medical Microbiology and Immunology for individuals interested in the genetic control of membrane development and biosynthesis. Postdoctoral applicants should send a completed curriculum vitae including three letters of reference. Postdoctoral salary will be $11,000-$12,000 per annum depending upon experience. Predoctoral applicants should write for information Both teaching and research assistantships are available.

All inquiries should be sent to S Kaplan, Department of Medical Microbiology and Immunology, University of Kentucky College of Medicine, A. B. Chandler Medical Center, MN-524 Medical Center, Lexington, Kentucky 40536.

The University of Kentucky is an equal opportunity employer F/M 9282(A)

GUY'S HOSPITAL MEDICAL SCHOOL

(University of London)

POSTDOCTORAL RESEARCH ASSISTANT

required to join a research group under Dr L. Mallucci in the Department of Microbiology investigating the role of cell surface membrane components in cell growth regulation and cell differentiation Position available to December 1979 with the possibility of further renewal of grant.

Salary in range £3,910 to £5,506 plus £450 London Allowance and superannuation.

For further details telephone Dr Mallucci

Applications to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT. 9055(A)

Synthetic Organic Chemists

Medicinal and Animal Health Research

We require two additional Ph.D. organic chemists with several years' experience at the post-doctoral level, who are able to demonstrate a sound record of creativity and who possess those personal qualities necessary to stimulate and catalyse good ideas with other members of the project team with whom they work.

Our projects are organised on multi-disciplinary bases and it is most important therefore that the successful candidates can think well beyond the purely chemical field and be able to originate synthetic programmes based on biological concepts. Effective communication with colleagues in other disciplines is vital. We would expect those appointed to be capable of organising and running a project of their own within the forseeable future.

The appointments carry starting salaries in the £6/8000 range and in addition to offering excellent career prospects there is good bonus potential. Pension, death benefit and salary continuance schemes are in operation, and there is generous assistance with relocation expenses to a pleasant coastal/rural area. Flexible hours are worked and the social/recreational facilities, which include squash, sailing, etc. are first class.

Pfizer

Applications from men and women, which will be treated in confidence, giving brief details of qualifications, experience, age, etc. should be sent to:

**D. W. Sells, Pfizer Central Research,
Sandwich, Kent, CT13 9NJ.**

9277(A)

MEMORIAL UNIVERSITY OF NEWFOUNDLAND

FACULTY OF MEDICINE

ASSISTANT PROFESSOR OF IMMUNOLOGY

Immunologist/Immunogeneticist required at Assistant Professor (and Postdoctoral fellow) level to join others in a medical school immunology group Special research strengths of this group are a good HLA lab (International workshop standard), complement allotyping, collaborative relationships with the blood bank, biochemical genetics, cytogenetics and with clinical investigators, plus the availability of large families Our group is also involved in teaching, in a clinical immunology diagnostic laboratory and with a transplantation programme

For more information please write, preferably sending detailed curriculum vitae plus any relevant reprints, to Dr W H. Marshall, Professor of Immunology, Faculty of Medicine, Memorial University of Newfoundland, Canada, A1B 3V6. 9137(A)

UNIVERSITY OF CAMBRIDGE

PROFESSORSHIP OF MATHEMATICAL PHYSICS (1967)

Applications invited for above Chair which will become vacant on October 1, 1979, by the resignation of Professor J C Polkinghorne. The Professorship is primarily assigned to the Faculty of Mathematics and the Professor will be accommodated in the Department of Applied Mathematics and Theoretical Physics Preference will be given to candidates whose work is conected with theoretical elementary particle physics.

Present pensionable stipend £10,939.

Applications (10 copies) marked 'Confidential' should be sent to the Secretary General of the Faculties, from whom further information may be obtained, at the General Board Office, The Old Schools, Cambridge CB2 1TT. Names of two referees may be submitted if desired.

Closing date: February 28, 1979. 9345(A)

We wish to appoint someone with experience in the medical or biological sciences to head a fully established research team in our Preclinical Research Department. The work of this team is mainly concerned with gerontological and pharmacological problems.

The person appointed will have a university degree in the medical or biological sciences backed by practical experience in the fields of anatomy, pathology or brain research. Importance is also attached to a knowledge of morphometry and/or stereology and to a good command of the English language.

Applicants are asked to send a short letter of application in the first instance to:

SANDOZ

Sandoz Ltd., Personnel Dept. Ref. 1200,
Postbox, 4002 Basle, Switzerland. 9321(A)

Cambridgeshire Area Health Authority (Teaching)

**Addenbrookes Hospital
Cambridge**

Applications are invited for the NHS post of

Senior Biochemist

in the Department of Clinical Biochemistry, which is comprised of both NHS and University elements. This post is primarily concerned with diagnostic services. The laboratory acts as a regional centre for a number of analytes and has excellent facilities for research. Candidates should possess a higher qualification and at least 4 years of relevant experience. Further training for final M.C.B. and M.R.C. Path. qualifications is available. Whitley Council conditions of service; salary scale £5,451 - £6,837.

Enquiries relating to the post and requests for application forms should be addressed to Professor C. N. Hale, Department of Clinical Biochemistry, Addenbrookes Hospital, Hills Road, Cambridgeshire, CB2 2QQ. Tel: 0223 45151. Ext. 7152.

The closing date for applications is March 1. 9294(A)

UNIVERSITY OF EXETER

CHAIR OF PHILOSOPHY

Applications are invited for the Chair of Philosophy, made vacant by the retirement, on September 30, 1979, of Professor D. J. O'Connor. No field of specialisation is prescribed for the Chair. Salary will be within the agreed professorial range, currently £9,443 minimum, £11,055 average, per annum (under review).

Further particulars should be obtained from the Academic Registrar and Secretary, University of Exeter, Northcote House, The Queen's Drive, Exeter EX4 4QJ. Closing date for receipt of applications (13 copies, overseas candidates 1 copy), February 26, 1979. Please quote reference number 3197. 9309(A)

Ph. D. DRUG METABOLISM

In recent years the discovery and development of new drugs has lead to an increasing demand for insight regarding their safety and mode of action. It has been recognised that the species differences in drug responses and toxicity which complicate the evaluation of drugs in laboratory animals can often be explained by corresponding species differences in the metabolism of the drug. Thus, the investigation of the absorption, distribution, metabolism and excretion of drugs in laboratory animals and man leads to a better understanding of the mode of action and toxicology. This briefly is the work of our Drug Metabolism Department.

We are now looking for an additional Ph.D with a broad understanding of pharmacology and drug research who has a strong desire to use this knowledge in drug discovery, and who wants to interact closely with multidisciplinary discovery teams.

The appointment, which is particularly suitable for a man or woman with 2/3 years post-doctoral experience, offers excellent career prospects, a competitive salary and good bonus potential. Pension, death benefit and salary continuance schemes are in operation and there is generous assistance with relocation expenses. Flexible hours are worked and the social/recreational facilities, etc., are first class.

Pfizer

Applications, which will be treated in confidence giving brief details of qualifications, experience, age etc., should be sent to:-

**D. W. Sells,
Pfizer Central Research,
Ramsgate Road,
Sandwich,
Kent CT13 9NJ** 9348(A)

Senior Research Position N/400

Basic research, preferentially in molecular genetics of eukaryotic systems, molecular immunology, cell biology or neurosciences. The position will be equipped with sufficient investment funds and with the possibility to start a group consisting of one technician, one postdoctoral coworker and students. University affiliation possible. Cooperation with existing groups in DNA repair, cell biology and mutagenicity desirable.

Applications should include a personal record, a list of publications and a brief description of intended research.

Postdoctoral position N/400

Biochemical and molecular characterization of immune deficiencies, within new research group: H. Ponta, H. J. Rahmsdorf and P. Herrlich. Applications should include a personal and scientific record including list of publications.

Deadline: March 1, 1979

Address: Kernforschungszentrum, IGT, Postfach 3640, D 7500 Karlsruhe, Germany.

**Kernforschungszentrum
Karlsruhe GmbH**

Experimental Scientists

Neutron Scattering Instrumentation.

Rutherford Laboratory.

A new intense source of pulsed neutron beams, the spallation neutron source is being built at the Rutherford Laboratory for use in research programmes of U.K. universities and polytechnics. A substantial number of neutron scattering instruments will be provided based on the time-of-flight method. A wide range of equipment and techniques is involved; for example, position sensitive detectors for epithermal neutrons; high resolution choppers; sample environments controlling parameters such as temperature, pressure, magnetic field; neutron guides; neutron polarisation systems.

There are vacancies in the Neutron Beam Research Unit for experimental scientists to participate in the development and provision of this equipment. As part of their development activities those appointed will have opportunities to work with research scientists using instruments at Harwell and the Institut Laue-Langevin, Grenoble. Applicants should have a degree in physics or applied physics, or an equivalent qualification, and preferably some experience in fields such as electronics, high vacuum, cryogenics. Appointments will be made to permanent positions in the Science Group at the level of Scientific Officer or Higher Scientific Officer.

Salary Scales: Scientific Officer £3,037-£4,724
Higher Scientific Officer £4,388-£5,829

Please apply to Jane Griffiths in the Personnel Group on Abingdon (0235) 21900 Ext. 510 or write to her quoting Reference No. VN 768.
Closing date for applications –16th February, 1979.

RUTHERFORD
Science Research Council
Rutherford Laboratory, Chilton, Didcot, Oxfordshire OX11 OQX. Tel Abingdon 21900

Botswana

Forest Officer

Up to £10,100 Plus Allowances

A graduate in forestry, preferably with 5 years relevant post-qualification experience, is required for the management of indigenous forests and the protection of forest resources in this developing African country.

Salary includes a substantial tax-free allowance paid under Britain's overseas aid programme. Basic salary attracts a 25% tax-free gratuity.

Benefits include free passages, generous paid leave, children's holiday visit passages and education allowances, subsidised housing, appointment grant and interest-free car loan.

The terms on which civil and public servants may be released if selected for appointment will be subject to agreement with their present employers.

For full details and application form write quoting MD/149/NA.

Crown Agents

The Crown Agents for Oversea Governments and Administrations, Recruitment Division,
4 Millbank, London SW1P 3JD

9350(A)

IMMUNOLOGIST/ VIROLOGIST

Two positions are available immediately at the Assistant Professor level for a Cellular Immunologist and a Virologist to work in the Bovine Leukemia Research Unit. Applicants should have a Ph.D. or D.V.M. degree with post-graduate training in the appropriate discipline.

Qualified applicants should send a résumé, copies of representative publications and the names of three people who may be contacted for references to: Dr Jorge F Ferrer, Chief, Section of Viral Oncology, University of Pennsylvania School of Veterinary Medicine, New Bolton Center, R.D 1, Kennett Square, Pa. 19348 9298(A)

FELLOWSHIPS

A RESEARCH FELLOWSHIP

tenable for a period of up to three years, is available for work on the regulation of eukaryotic genes by steroid hormones. Emphasis will be given on the isolation, cloning and characterisation of specific genes. Candidate should be experienced in the techniques of nucleic acid biochemistry. Applications (with curriculum vitae) should be sent to Dr J.-P. Jost, Friedrich Miescher-Institut, P O Box 273, CH-4002 Basel, Switzerland

9227(E)

UNIVERSITY OF EXETER

DEPARTMENT OF PHYSICS

POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited from suitably qualified persons for an S.R.C. Postdoctoral Research Fellowship. The successful candidate will conduct research in Low Temperature Physics working with Professor A. F. G. Wyatt and Dr D. R. Allum. The experiments involve propagating high frequency phonons through liquid helium cooled by a dilution refrigerator. Present studies include a precise phonon group velocity measurement, angular phonon acceptance at a single crystal interface, non linear effects in the helium and at interfaces and atomic desorption by phonons.

The grant has been awarded for three years and the post is to commence as soon as possible.

Commencing salary will be in the range £3,883 to £4,382 per annum. The post is superannuated.

Further particulars may be obtained from Professor A. F. G. Wyatt, Department of Physics, University of Exeter, Exeter EX4 4QL, to whom applications, two copies (one copy from candidates living overseas) and the names of three referees should be sent by February 21, 1979 9325(E)

UNIVERSITY OF WARWICK

RESEARCH FELLOWSHIP IN VIROLOGY

Applications are invited for a Postdoctoral Fellowship in the Tumour Virus Research Group in the Department of Biological Sciences. The successful applicant will work in a small group studying the biochemistry of C type RNA tumour viruses, with particular reference to their ability to transform cells. Experience of nucleic acid technology and in particular the use of *in situ* hybridisation techniques, while not essential, would be an advantage. Starting salary will be between points 1 and 6 on the Research 1A scale £3,883 to £6,555 per annum. The Fellowship (funded by the Medical Research Council) is available from March 1, 1979 and is renewable on an annual basis until September 1981. Further details and application forms from the Academic Registrar, University of Warwick, Coventry CV4 7AL quoting Ref No. 24/2A/79. Closing date for receipt of applications is February 15, 1979. 9269(E)

UNIVERSITY OF CAMBRIDGE

Broodbank Fellowships

Applications invited for Fellowships for full time research normally at Cambridge in Biochemistry or Biophysics with special reference to the principles and practice of food preservation. Tenure normally from October 1, 1979, for one year first instance but may be extended for one or two further years. Candidature open, but preference for post-doctoral applicants. Pensionable salary for postdoctoral Fellow in range £3,425 to £5,058 according to experience and qualifications. Compulsory superannuation.

Applicants should ascertain that there is a laboratory in Cambridge willing to accommodate them and must outline research proposed indicating bearing on principles and practice of food preservation and include full curriculum vitae, copies of papers published or references thereto and names and addresses of at least two referees.

Full details available from and applications (ten copies) to reach the Secretary to the Managers of the Broodbank Fund, Department of Applied Biology, Pembroke Street, Cambridge CB2 3DX not later than March 1, 1979. 9261(E)

FELLOWSHIPS—continued

Commonwealth of Australia

QUEEN ELIZABETH II FELLOWSHIPS

Physical & Biological Sciences

To commemorate the Royal Visit to Australia in 1963 the Australian Government established the Queen Elizabeth II Fellowships scheme. Under this scheme up to ten fellowships may be awarded each year for full-time research by young scientists of exceptional promise and proven capacity for original work. These are post-doctorate awards tenable in an Australian university or approved research institution normally for two years. Tenure of a Fellowship is expected to commence within nine months of the announcement of the award.

QUALIFICATIONS: Queen Elizabeth II Fellows must be either Australian or United Kingdom citizens. They should have a Ph.D., or equivalent qualifications, in one of the physical or biological sciences (which are deemed to include mathematics and the scientific aspects of statistics, engineering, metallurgy, agriculture and medicine). Awards will, in general be restricted to applicants who are not more than 30 years of age on the date when applications close. Applications will also be considered from candidates for the Ph.D. degree if their thesis has been submitted for examination.

STIPEND: $17 131 (Australian) per annum – increased to $18 403 per annum at age of 28 years.

ALLOWANCES: Are payable in respect of a Fellow's dependent spouse ($500p.a.) each dependent child ($200), superannuation payments (up to 10 per cent of stipend), appropriate insurance coverage and necessary travel expenses.

APPLICATIONS: *Persons interested in applying for the above fellowships should obtain application forms and a statement of the conditions of award from the Secretary, Queen Elizabeth Fellowships Committee, Department of Science, P.O. Box 449, Woden A.C.T. 2606, Australia: the Minister (Scientific), Canberra House, 10–16 Maltravers Street, London, WC2R 3EH, U.K.; or the Australian Embassy, 1601 Massachusetts Avenue, Washington D.C. 20036, U.S.A. Applications for the next round of awards, which will be announced in June 1979 close at the Canberra address on 16 March 1979.*

9323(E)

EMBO

European Molecular Biology Organization

LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY

SPRING 1979 AWARDS

Next deadline: February 20, 1979

The long term fellowships will usually be for a period of up to one year but applications for a renewal for a second year are considered. To be eligible a candidate must hold a doctor's degree. Preference will be given to European and Israeli applicants wishing to work within Europe or Israel. EMBO long term fellowships are **not**, however, awarded for exchanges between laboratories within any one country. Applications for fellowships to be held outside Europe and Israel are considered but they have a lower priority, as do applications from non-European scientists wishing to work in Europe or Israel.

The deadline for applications for the 60 fellowships to be awarded in April 1979 is February 20, 1979. Because the selection procedure involves an interview this deadline should be respected.

Application forms and further details may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 1022.40, F.R. Germany. 9278(E)

THE ROYAL SOCIETY

LOCKE RESEARCH FELLOWSHIP
ROSENHEIM RESEARCH FELLOWSHIP

Applications are invited by the Council of the Royal Society for:

(a) A Locke Research Fellowship for research in experimental physiology and pharmacology.

(b) The Rosenheim Research Fellowship established under the will of the late Mrs M. C. Rosenheim for research on the biochemistry of plants and the simpler forms of animal life. Preference will be given to candidates wishing to study the biochemistry of higher plants.

Both appointments are tenable in any appropriate university department or research institution approved by the Council of the Royal Society (the Rosenheim Research Fellowship is restricted to places in Great Britain). Candidates should supply the usual personal details and two referees. Testimonials will not be considered. The subject of the proposed research and where it will be done, together with the name of the head of the department, whose consent should first be obtained, must be stated.

The appointments, which will be subject to the Society's general regulations governing research appointments, will be tenable for three years in the first instance from October 1, 1979, and may be renewable for a further two years, such renewal being considered at the end of the second year of tenure. Applicants should preferably be under 33 for the Locke Research Fellowship and under 26 for the Rosenheim Research Fellowship on October 1, 1979. Stipend scales are as follows (the point of entry will be determined by Council), and superannuation benefits are provided:

Locke Research Fellowship (Category C): £6,153 by £240 to £7,113 by £243 to £7,356 per annum.

Rosenheim Research Fellowship (Category D): £4,461 by £249 to £5,706 per annum.

Applications should be made on forms to be obtained (stating name of Fellowship) from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG, and should be received not later than February 28, 1979. 9275(E)

POSTDOCTORAL RESEARCH ASSOCIATE

required to work on DNA-protein interactions, on the structure of chromatin in Dr J. G. Brahms' research group, in Paris. The group has a computerised Raman Laser spectrometer, vacuum U. V C. D. and other equipment and is actively engaged in structural and functional investigation on DNA and protein interaction in chromatin Some research experience in biochemical and biophysical techniques is desirable. Fellowship starting £5,000 per annum.

Application indicating training and research experience should be sent to Dr J. G. Brahms, Institut de Recherche en Biologie Moléculaire (Tour 43) 2, place Jussieu—75005 PARIS—France. 9266(E)

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF CHEMISTRY

Applications are invited for a

POSTDOCTORAL RESEARCH FELLOWSHIP

in the Department of Chemistry, Southampton University. The person appointed will work with Dr B. Cleaver on a Science Research Council supported project to study the influence of high pressure on miscibility in high temperature liquid systems (molten salts and molten metals), at pressures up to 25 kbar and temperatures to 1,200 °C. The experimental work will be carried out mainly at Southampton, but will also involve the use of a new high pressure facility at the National Physical Laboratory, Teddington, for a six month period.

Applicants should hold a Ph D degree and should have experience in at least one of the following fields: molten salt chemistry; high pressure technology; thermodynamics of liquid systems. A driving licence would also be an advantage.

The post is available for two years, starting immediately. The starting salary will be in the range £3,883 to £4,382 (under review), depending on age and experience. Applications with curriculum vitae and names of two referees, should be sent to Dr B. Cleaver, Department of Chemistry, University of Southampton, from whom further particulars can be obtained. Please quote reference number 1608/R/Na. 9310(E)

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF PHYSICS

RESEARCH FELLOWSHIPS IN CRYOGENICS

Applications are invited for postdoctoral fellowships to work on the following projects:

(1) Heat transfer in the reboiler/condensers of cryogenic plant, using model rigs and a full length test section.

(2) Complex convective flow in stratified cryogenic vapours and liquids using Laser Doppler Anemometry.

(3) Heat transfer and fluid behaviour of helium at 3,000 r.p.m. for the development of large superconducting machines.

Applications should have experience in mechanical/chemical engineering or low temperature physics

Salary in range up to £5,367 plus U.S.S. benefits.

Applications with names of two referees should be sent to Mrs E. C P. Sears, Staffing Section, The University, Highfield, Southampton SO9 5NH. Please quote reference no. 1607/R/Na. 9290(E)

STUDENTSHIPS

MEDICAL RESEARCH COUNCIL

National Institute for Medical Research

POSTGRADUATE STUDENTSHIPS

The National Institute for Medical Research has positions for postgraduate students to study towards the degree of Ph.D. The fields of interest are broadly those covered by the following divisions and laboratories of the Institute, namely: Bacterial Infectivity, Biochemistry, Biophysics, Developmental Biology, Endocrinology, Genetics, Immunology, Leprosy and Mycobacterial Research, Microbiology, Molecular Pharmacology, Neurobiology, Neurophysiology and Neuropharmacology, Peptide Chemistry, and Virology.

The Institute invites applications from students in their final year in all branches of the physical and biological sciences. In general, approximately ten positions are available each year

For further information and application form please write stating your research interests to: Dr J. B. Ward, Director of Studies, National Institute for Medical Research, The Ridgeway, Mill Hill, London NW7 1AA. 9333(F)

BRITISH MUSEUM (Natural History)

POSTGRADUATE RESEARCH STUDENTSHIPS 1979

Three studentships will be available, tenable for 3 years, at the British Museum (Natural History) and commencing October 1979.

Arrangements will be made with an appropriate university for higher degree registration and joint supervision of the research project.

The research projects for which applications are invited are as follows:—

DEPARTMENT OF BOTANY

1. Fine structure and cytochemistry of reproduction in the seagrass *Zostera*.

DEPARTMENT OF ENTOMOLOGY

2. Phylogenesis of *Danaus* butterflies, as demonstrated by numerical taxonomy, hybridisation and Hennigian phylogenetic systematics.
3. Comparative anatomy of the reproductive system in aphids.

DEPARTMENT OF ZOOLOGY

4. Taxonomy and zoogeography of polymorphic cyclopoid copepods.

Facilities are available for scanning and transmission electron microscopy serology, biochemistry and biometrics In addition, students will have access to the Museum's extensive library.

ELIGIBILITY

Applicants to be aged 27 or less, ordinarily resident in Great Britain, and to have a first or upper-second class honours degree; students graduating in 1979 can be offered awards subject to their degree results reaching this level.

Students interested in applying should write to the Secretary (Postgraduate Studentships), British Museum (Natural History), Cromwell Road, London SW7 5BD, for application forms, conditions of the awards, and for further information on projects.

Closing date for receipt of completed applications forms—March 18, 1979.

8249(F)

MEDICAL RESEARCH COUNCIL

National Institute for Medical Research

LABORATORY OF PEPTIDE CHEMISTRY

Applications are invited for a Science Research Council

C.A.S.E. STUDENTSHIP

to work with Dr D. G. Smyth on the synthesis and metabolism of novel analogues of peptides which occur in brain and pituitary. The project is sponsored by the Pharmaceutical Division of Reckitt and Colman and is tenable from October 1, 1979.

Applicants should be chemists or biochemists and should have, or expect to obtain, a good honours degree or equivalent. The successful applicant will be expected to enrol for a Ph.D. degree at the University of London

For further details please write as soon as possible to the Director of Studies, National Institute for Medical Research, Mill Hill, London NW7 1AA, enclosing curriculum vitae and the names of two referees 9332(F)

UNIVERSITY OF ESSEX

DEPARTMENT OF CHEMISTRY

Applications are invited for an

S.R.C. C.A.S.E. RESEARCH STUDENTSHIP

tenable for three years on the "Initiation of Liquid Hydrocarbon/Air Mixtures": in collaboration with Shell Research Limited, Thornton Research Centre, Chester.

Projects will be supervised by Professor J N. Bradley, from whom further details are available. Applications should be sent to Professor Bradley, Department of Chemistry, University of Essex, Wivenhoe Park, Colchester, as soon as possible.

9296(F)

University of Wales

UNIVERSITY COLLEGE OF SWANSEA

C.A.S.E. STUDENTSHIP

Applications are invited from persons holding, or expecting to obtain, a good honours degree in chemistry for a C.A.S E. Studentship in organic chemistry research towards the degree of Ph.D. on the project, **Oxidative Methods of Aromatic Substitution,** in collaboration with I.C.I (Organics Division). The project involves the synthesis of heterocyclic organic compounds by oxidative methods —e.g. electrochemically or by metal ions. The compounds will be of particular interest to the dyestuffs industry.

Further details are available from Dr T W. Bentley, Department of Chemistry, University College of Swansea, Singleton Park, Swansea SA2 8PP, to whom applications should also be sent along with curriculum vitae and the names of two referees. 9338((F)

SYMPOSIA

STRAW DECAY SYMPOSIUM

April 10, 11, 1979

HATFIELD POLYTECHNIC

HATFIELD

Topics: Effects of straw residues on germination pathogens, fauna.

Decay on or in soil, mushroom composts, rumen. Improvement for animal feed, anaerobic digesters, Microbiological and Biochemical aspects.

Contact: **Grossbard, Hatfield Polytechnic, Bayfordbury House, Hertford. Tel: 53067.** 9336(M)

SYMPOSIA—continued

NATO
Advanced Study Institute on the ENVIRONMENTAL PHYSIOLOGY OF FISHES

12th to 25th August, 1979
near MONTREAL,
QUEBEC, CANADA

This ASI will deal with the chemical and physical environmental factors in the physiology of fishes and total responses such as behaviour and rhythms The main body of the ASI will be review lectures and about 25 per cent of the time will be allotted to the presentation of short seminars by some of the selected participants. Lecturers will be: R Gilles (Liège), P. Dejours (Strasbourg), G. Sundnes (Trondheim), K. F. Liem (Harvard), N. Heisler (Goettingen), D. H Evans (Miami), E. Skadhauge (Copenhagen), G. F. Holeton (Toronto), S. Bjornsson (Reykjavik), T. Tamura (Nagoya), B Baggerman (Groningen), J. N Lythgoe (Bristol), W W Reynolds (Pennsylvania), T. Dale (Bergen), A N Popper (Georgetown), J H S Blaxter (Oban), A. J. Kalmijn (Woods Hole), F. E. J. Fry (Toronto), P. Enger (Oslo), F. W Tesch (Hamburg), H. O Schwassmann (Florida) and M A Ali (Montréal).

The number of participants will be restricted to a maximum of 100 and everyone selected will be expected to spend the entire duration at the ASI Application forms may be obtained from:

Professor M. A Ali
Départment de Biologie
Université de Montréal
C. P. 6128, Station "A"
Montréal H3C 3J7 Canada

Selection will be made by the end of March 1979 and those selected will be asked to provide a non-refundable deposit of $50 which will be deducted from the living expenses of $275 00 Application may also be made in the form of a letter giving a short curriculum vitae, present scientific interest and the name of a referee

A limited number of grants, to cover partially the living expenses and travel costs, are available to participants from NATO countries but participants are encouraged to cover expenses from the resources of their own institutions wherever possible.

MISCELLANEOUS

CHINA: SCIENCE AND SOCIETY

SACU's 21-day SCIENCE STUDY TOUR leaves March 18, an unusual opportunity to see China and study the rapidly-changing role of science and technology in Chinese society. Assess China's achievements in advanced research, the popularisation of science and the use of 'appropriate' technology.

CHUNGKING AND THE YANGSTE GORGES

SPECIALIST TOUR in August with varied coverage for Geographers and Environmentalists, visiting Peking, Wuhan, Canton and Szechuan province, whose mountains enclose the famous Red Basin, and three-day investigative trip through the Yangste Gorges.

Full preparatory study programme.

Details of 1979 tour programme: Society for Anglo-Chinese Understanding, 152 Camden High Street, London NW1 0NE, 01-267 9841.

9279(J)

ASSISTANTSHIPS

QUEEN ELIZABETH COLLEGE
Kensington
(University of London)
RESEARCH ASSISTANT
in the
DEPARTMENT OF FOOD SCIENCE AND NUTRITION

Applications are invited for a research assistantship sponsored by the Agricultural Research Council for a period of 12 to 14 months, to work on the stability of food emulsions containing milk proteins. Applicants should have a good honours degree in Chemistry, Food Science, Physics, or other appropriate discipline.

Salary up to £3,909 p a (depending on experience) plus London allowance of £450 p.a.

Applications should be sent as soon as possible to Dr P. Sherman, Department of Food Science and Nutrition, Queen Elizabeth College, Campden Hill Road, London W8 7AH

9329(P)

SUNDERLAND POLYTECHNIC
FACULTY OF SCIENCE
DEPARTMENT OF PHYSICAL SCIENCES
S.R.C. POSTDOCTORAL RESEARCH ASSISTANTSHIP

A two year appointment is available with a small group studying high temperature and photochemical reactions of heterocyclic compounds. The project sets out to extend the preparation and chemistry of heterocyclic analogues of biphenylene, and other aspects of synthesis and mechanism at high temperature.

The starting salary is £4,130 per annum and the starting date by arrangement between April 1 and September 30, 1979. For further details please contact Dr J A H. MacBride, Chemistry Division, Department of Physical Sciences, Sunderland Polytechnic, Chester Road, Sunderland SR1 3SD. Telephone Sunderland 76191, Ext. 147.

...Run...

It's all very well being poker-faced when the question of safety is raised . . . but when disaster looms and the only advice is "Run"! you must admit that things are a little out of hand. Take the gamble out of work in the laboratory . . . make sure you always have a full house . . . keep yourself informed about safety regulations and requirements.

BDH has a wide range of wall charts and safety aids for the laboratory, ask for details . . .

Spot the Difference

Sephacryl® S-200
Superfine
750 ml
Pharmacia Fine Chemicals
Pharmacia Fine Chemicals AB Uppsala, Sweden
Lot No. 5839
Wet bead diameter: 40—105 µm
Sephacryl® S-300
Superfine
750 ml
Pharmacia Fine Chemicals
Pharmacia Fine Chemicals AB Uppsala, Sweden
Lot No. 3792
Wet bead diameter: 40—105 µm

Sephacryl®

the different medium for gel filtration

- Faster separations: Sephacryl has speed and resolution to spare; separates proteins 5–10 times faster than conventional media.
- Faster packing: Sephacryl is pre-swollen, ready-to-use and packs fast.

Use Sephacryl S-300 Superfine for separations up to an exclusion limit of 1.5 million for globular proteins; ideal for serum proteins. Use Sephacryl S-200 Superfine up to an exclusion limit of 250,000 for globular proteins.

When you use Sephacryl, the difference is clear. Find out more about Sephacryl from your usual supplier of Sephadex®, Sepharose® and other separation media.

M MACMILLAN PRESS

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. **Letters** should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**, 1 (1975) and **264**, v, 11 Nov. (1976).

Bang!—you're seriously injured

WHAT constitutes inhumane weaponry? Some, doubtless dismissed as soft-headed do-gooding pacificists, might wonder whether humanity can solve any dispute by projecting a small metal object at a velocity of up to 1 kilometre per second into the body of an adversary causing all manner of totally unpredictable damage. But so sated are we, as a culture, with letting the disagreements of individuals, groups and nations be settled by technological means totally unrelated to the merits and demerits of the case in question that the issue of just what weapons a nation can acceptably deploy has had to be faced for more than a century, and will be the subject of a United Nations conference later this year.

The St Petersburg Declaration of 1868 was the first international agreement on the subject, and its principles are worth repeating even today. They state that the only legitimate objective should be to weaken the military forces of the enemy, and for this purpose it is sufficient "to disable the greatest possible number of men". They go on to state that it would be contrary to the laws of humanity to exceed this objective by employing arms which "uselessly aggravate the sufferings of disabled men or render their death inevitable". The principles that military actions should not be indiscriminate, particularly avoiding civilians, and that weapons which cause injuries having no military utility should be banned, have continued to be at the centre of conferences ever since. In 1907 (in response to the threat of chemical warfare) the concept was added at the Second Hague Peace Conference that cruel and repulsive weapons, even with military utility, should also be prohibited. Needless to say these ideals have been widely ignored.

SIPRI, the Stockholm International Peace Research Institute, today publishes a valuable guide to the subject of inhumane warfare. *Anti-personnel Weapons* (Taylor & Francis, £9.00) by Dr Malvern Lumsden, a researcher at SIPRI, is an attempt to bring together all the scattered information available about ammunition, grenades, bombs and mines used primarily against people rather than matériel. This is done within a historical framework, making it particularly easy to see the evolution of weaponry and attitudes. Dr Lumsden also includes a brief discussion on emerging methods such as acoustic and laser techniques.

The St Petersburg Declaration was in part a response to a general concern in the mid-nineteenth century that exploding bullets might come into general use, but already by then conical bullets were inflicting more severe wounds than older spherical ammunition, and it was beginning to be noted that bullets could be designed to splay out on encountering an obstacle. Eventually, of course, this led to the Dum-Dum bullet, having a soft metal nose which expanded on penetration, causing extensive internal damage. Britain argued for the Dum-Dum bullet in colonial operations at the Hague conference of 1899, saying that whilst soldiers were incapacitated by a single projectile, "the savage, although run through two or three times, does not cease to advance"; hence the need for a more damaging bullet. But the conference reaffirmed the need to avoid superfluous injuries.

Twentieth century warfare has been somewhat different. Certainly bullets have continued to be widely used and many of these, fired from lighter weight rifles, have been of smaller calibre. This diminishes effectiveness if the bullet just drills a narrow hole through the body, but if it can be made to tumble and even fragment within the body, damage levels can be greatly raised. All current bullets are capable of causing this damage, which is reminiscent of that from the explosive bullets of the 1860s. But rifle and machine gun fire has been less successful during the First World War and subsequently at disabling the enemy so much as at containing him, up to fifty thousands rounds may be expended in modern warfare for every hit made.

In the meantime, fragmentation weapons have grown in importance until now they account for 70% of all casualties. Recent trends in bombs, grenades and shells have been to design delivery systems which disperse large numbers of small fragmentation weapons over a wide area, and to increase the number of fragments produced from individual explosions. Furthermore, weapons can be made to burst just above the ground, say at eye level.

Fragmentation weapons raise questions concerning indiscriminate use. Some can be delivered accurately but many are sufficiently widely scattered that there can be no guarantee that civilians are not equally victims of them. Delayed-action devices such as mines fall into the same indiscriminate category, often being triggered months or even years later by a non-combatant. It would be possible, however, to incorporate a neutralising device in a mine to put it out of action after a given time.

Dr Lumsden reports on these and many other devices which have been used or at least investigated, such as fuel-air explosives, concussion bombs, flechettes, toxic bullets, baton rounds, rubber bullets and so on. He describes them all dispassionately, in the best SIPRI tradition, and the book deserves to be read and thought about by a wide range of people who would not normally give serious attention to conventional warfare.

What, then, are the general questions confronting international discussions? First one must ask whether it is really possible to walk at all on the knife-edge between acceptable and unacceptable warfare. Can a line be drawn between serious injury from a tumbling bullet and death from a non-tumbling one? And can civilians and military forces really be distinguished in modern guerilla warfare? As Lumsden points out some of the problems of fair and foul fighting were faced up to during the United States' involvement in Indo-China, and the Rules of Engagement at that time deserve serious study as a basis of a way forward. Second, what is it in us that regards chemical weapons as crueller even than nuclear weapons and much crueller than guns and bombs—and is there any possibility that public opinion could in future be made to regard nuclear and conventional warfare as equally cruel? Third, is it best that we convene technical and medical conferences for precise definitions of prohibitions, a small step forward for arms control, or put all our effort into more extensive but more inaccessible measures of disarmament? ☐

US scientists to join Italians in dioxin study

An announcement is expected later this month of a joint scientific investigation into the health implications of exposure to dioxin. **Alastair Hay** reports on the protracted negotiations leading to this decision.

In February the US National Academy of Sciences (NAS) will announce the formation of a binational study group to consider the public health consequences of exposure to 2,3,7,8-tetrachlorodibenzodioxin (dioxin) Behind the decision to form the group—composed of equal numbers of Italian and American scientists—lies a history of nearly two years of discussion, negotiation and some doubt as to the value of what was seen by some as nothing more than yet another committee looking into the dioxin problem.

The initiative to form the study group was taken by the NAS shortly after the accident at Sévéso in Italy in July 1976 when dioxin from a trichlorophenol reactor was discharged over a populated area In the words of one prominent Italian scientist, the NAS wrote to the National Research Council in Italy recommending a study of Sévéso. The suggestion was couched in terms of the NAS "offering help to Italy"

It seems however, that, at that time, Italian scientists were not over-eager to conduct the study proposed by the NAS. The letter which the NAS sent went unanswered until a senior Italian scientist happened to see it by accident Recognising its potential importance he brought it to the attention of the Minister of Health urging him to reply favourably and to invite the NAS to send a team to discuss the proposition

The team, led by Norton Nelson, Professor of Toxicology at New York University, visited Italy in early April 1977.

When it returned, it made several recommendations including suggestions for developing a continuing relationship between US scientists and their Italian counterparts; the exchange of scientific and technical literature; the initiation of complementary research; and the organisation of workshops and exchange visits. It was suggested that the US programme be operated under a small steering group appointed by the NAS and its own National Research Council and that it relate to an 'appropriate counterpart' committee on the Italian side.

These recommendations were subsequently sent to Italy for approval together with a request for the names of the Italian scientists who would be participating in the programme According to the NAS the matter then 'lay dormant' until late January 1978 when a reply was received from Dr Pocchiari, Director of the Istituto Superiori Di Sanita in Rome, naming the Italian members and requesting the formation of the NAS counterpart committee

It seems to have been some months before the NAS prepared its final programme for which it sought funding The project it proposed was to be conducted in several phases, the first being simply a review of the situation Subsequently the study groups activities might include "design and evaluation of medical follow-up studies, methods, and design of systems for emergency response to similar accidents" Thus the NAS made it quite clear that it would consider a range of issues stretching beyond Sévéso Indeed, in its proposal the NAS Assembly of Life Sciences said that it would try to "develop guidelines and approaches to handling of future tragedies, and to the forecasting of potential environmental disasters".

Norton Nelson, who will be one of the US members of the study group, qualified the last proposal by saying that he is always wary of "cookbook recipes for accident prevention in future" and that he would be content if the joint programme merely provided some general guidelines for action.

With no funds of its own to implement the joint study programme, the NAS sought support from several other sources. According to an NAS spokesman the programme—which will last initially for two years—has been funded with some $120,000 by the Environmental Protection Agency, National Institute for Environmental Health Sciences and the Centre for Disease Control. Asked if F. Hoffman la Roche—the parent company which owns the reactor at Sévéso—had been approached for funds as well the spokesman insisted that it had not. One of the US study group members added that Roche would be "amongst the last we would approach" for support.

The National Academy, however, did consider asking Roche for funds, early in 1978 When informed about the NAS's suggestion to approach Roche the Italian government made it quite clear that it would have no part in the study if the company played any part in funding it. Embarrassed at having considered such an approach and anxious to avoid the cancellation of its programme the NAS had to seek its finance from alternative sources.

The NAS committee members have "not yet met", according to Nelson, but will do so in early February Following this meeting the US scientists will then meet with their Italian counterparts. "Out of that meeting we hope to formulate a programme of action", said Nelson.

Sorting out that programme could be a delicate exercise. If, as one Italian scientist put it, "it is just a NAS study in Italy, then that is very difficult and complicated On the other hand, an international study is fine" What the Italians are looking for is a clear definition of the terms of reference of the NAS study.

One of the proposals of the NAS is that an epidemiology panel be set up. But one senior Italian scientist said that although the health surveillance programme of the Sévéso residents conducted by the Lombardy Regional Council had been less than successful he was "not sure that a new epidemiological study would work"

The protracted nature of the negotiations to establish the study group has left one of the Italian group members less than enthusiastic about the proposals, particularly as the situation at Sévéso has changed so much One other criticism of the binational study group, advanced by some scientists, is that it is yet another committee set up to consider dioxin. Italian scientists say that the International Agency of Cancer (IARC) was to coordinate all information on dioxin yet that they have heard no more from the IARC

Nelson denies that there will be any "duplication of effort" He says that both the IARC and World Health Organisation know about the NAS proposals and will be kept thoroughly informed

Of one of the anxieties expressed by Italian scientists that the NAS progremme could be read as a criticism of their own activities at Sévéso, Nelson said that this should not be the case He felt that after the two week delay in evacuating the residents of Sévéso, the authorities had acted swiftly The NAS said Nelson had "no complaints about the handling of the situation by the Italians"

The binational study group has recently been described by one US scientist as a "committee of good intentions" Many other US scientists hope that it will be more than this and they seem relieved that the programme has actually got off the ground at last ☐

Hope for UNCSTD in New York

David Dickson reports from New York on the third meeting of the preparatory committee for the United Nations Conference on science and technology for development

WITH less than seven months to go until the United Nations Conference on Science and Technology for Development (UNCSTD) opens in Vienna the political pace of preparations is beginning to heat up with indications that the conference may not turn out quite so unproductive as some have been fearing.

The most positive indication, according to a number of delegates attending the third meeting of the conference's preparatory committee, which opened in New York last week, is a new draft preliminary programme of action prepared by the conference secretariat.

The new draft, although still felt by many to suffer a number of important omissions—such as adequate discussion of the role of women in development, or the need for appropriate technologies—is widely accepted as a major improvement on earlier versions, which had been little more than the compilation of suggestions made in national and regional papers.

In particular, the new draft contains—as the General Assembly of the United Nations has said that it should—a number of specific recommendations for action around which discussion is likely to focus in the months ahead.

Opening the committee meeting last week, Dr Joao Frank da Costa, Secretary-General of the conference said that it was often more difficult to elaborate principles than to elaborate specific action-oriented measures, and that he therefore suggested concentrating on the latter rather than the former.

In particular, Dr da Costa said it would be necessary to develop firmer guidelines on cooperation between developed and developing countries, while the developing countries themselves, for which UNCSTD was a "now or never opportunity", should investigate ways of increasing their collective self-reliance.

The preliminary draft programme of action, which will be revised following comments by delegates at the New York meeting, contains both a theoretical and conceptual framework for further actions based largely on the outcome of debates, within the UN system, on the shape of the new international economic order, as well as over one hundred concrete measures for action at all levels.

Most of the recommendations are relatively uncontroversial. They include the suggestion that the developed countries increase the amount of money they spend on research into the problems of developing countries, and that the latter should establish national science and technology policies—drawn up and executed by governments, though with the advice of broadly based national science and technology councils representing all sectors of society—and establish institutions for assessing the impact of transferred technology.

More likely to generate controversy are recommendations which would involve setting up new international funds. The draft, for example, suggests that developing countries should establish a common science and technology fund "to which the most prosperous among them should contribute more generously", and that consideration also be given to a "risk capital fund" associated with existing financial institutions within the UN system.

Equally controversial are suggestions that to go beyond the domain of science and technology to comment on more overtly political issues Paragraph 11 12, for example, suggests that in parallel to mobilising science and technology for development, "countries should introduce internal structural policies such as social reforms, redistribution of income and so on, as appropriate, so as to ensure that the application of science and technology does not result in social tensions".

How many such suggestions will survive the revision process remains to be seen. Of particular interest is whether the developing countries, through the group of 77, will be able to agree on a common set of demands. A working party established last week by the group is said to have had initial difficulty reaching a consensus But the more coherent their position, according to observers in New York, the more likely that controversial issues will stay on the UNCSTD agenda ☐

US paper stresses modernisation and meeting basic human needs

THE modernisation of developing economies, and meeting the basic human needs of developing country populations are the two over-riding objectives in applying science and technology to development, according to the US national paper for UNCSTD.

In the introduction to the paper, Father Theodore Hesburgh, previously president of Notre Dame University and chairman of the US delegation to the conference, says that these two goals are not mutually exclusive or incompatible. "The fulfilment of basic needs and the process of economic moderation can proceed simultaneously in a mutually enforcing relationship," says Father Hesburgh.

The US paper, which has gone through numerous drafts and is yet to be officially released, describes the role played by science and technology in the growth of the US economy, as well as the US's experience in applying scientific and technological expertise to the problems of development in other nations.

The paper points out that President Carter has made scientific and technological cooperation a key element of the US's relationship with other countries, particularly in the developing world. It says that the success of the developmental process in other nations is "very much in the US interests."

The paper lists recommendations for action in six areas:

- ● Improving the capacity of industrialised countries to assist developing countries upgrade their scientific and technological skills;
- ● Assisting the development of education and training programmes;
- ● Encouraging collaborative research between scientists and engineers from both developed and developing nations on global problems such as food, water and health;
- ● Helping to overcome obstacles to developing countries' access to scientific and technological information;
- ● Strengthening the links between the research communities of developed and developing nations, including joint research and problem solving;
- ● Building a more effective UN system for science and technology.

The US paper puts forward the Foundation for International Technological Cooperation, which has been proposed by President Carter, as one way in which scientists from the developed and developing nations could work together, and suggests that the UN conference "should encourage the establishment of similar institutions in other countries".

The paper also says that the many useful science and technology activities within the UN system need a central focal point and policy direction, although, it adds, not a new entity. ☐

Brazil bans conference on Amazon biology

The Amazon: science can help protect its environment

THE Brazilian government has refused permission for a conference on the evolution of biological systems in the Amazon region, organised by the Association for Tropical Biology, which was to have opened next week in Manaus, the region's major city.

Although no official reason for the decision has been given, scientists in the US believe that the military government may have been concerned that those attending the meeting would use it as an occasion to criticise the environmental effects of Brazil's current development policies—even though the conference itself will deal primarily with events that took place over 5,000 years ago.

The conference has been hastily rearranged to take place in Macuto, on the Venezuelan coast outside Caracas, and has received the support of the Venezuelan Ministry of the Environment. It has been convened to discuss biological models of diversification in the tropics. Speakers will address topics such as the relationship between climatic change and species differentiation in the Amazon and its surrounding savannah region.

All the original speakers—including a number from Brazil—are expected to attend as planned. However, the change of location may prevent the participation of some Brazilian research workers and students, for whom lengthy visa negotiations, as well as the deposit of a large sum of money, are necessary for foreign private travel.

"This conference will bring together specialists in disciplines ranging from archaeology to entomology and genetics. Everything is now working together, and we are coming up with some exciting material, such as the correlation between archaeological sites and past climatic changes," Dr Clifford Evans, curator of South American archaeology at the Smithsonian Institution in Washington, DC, and one of the main organisers of the conference, said last week.

The military government's decision, which was taken on the advice of the National Security Council, has provoked a storm of protest in the Brazilian press, from which censorship has only recently been lifted. Critics, including a number of eminent scientists, have accused the government of interfering with academic freedom, and of ignoring how science is necessary to preserve the environmental integrity of the Amazon region.

David Dickson

Second thoughts on study of nuclear risk

THE Boston-based Union of Concerned Scientists has called for the temporary shutdown of 16 US nuclear power plants for safety modifications, in the light of evidence that previous estimates of "low probability" risks may have been unjustified.

This demand follows the decision of the Nuclear Regulatory Commission to withdraw its support from important parts of a study published by the commission three years ago on the safety of nuclear reactors, which indicated that the risks from nuclear power were much less than from other man-made activities.

The study was carried out for the NRC by a team headed by Professor Norman Rasmussen, of the Massachusetts Institute of Technology. On its publication in 1975, the NRC described the report as a "soundly based and impressive work".

The conclusions of what has become widely known as the Rasmussen Report have been frequently used by supporters of nuclear power to defend existing and proposed programmes. However, criticism by others of the report's methodology and its conclusions—in particular by Congressman Morris Udall, chairman of the House Committee on Interior and Insular Affairs—led the NRC to appoint a review group headed by Professor Harold Lewis of the University of California, Santa Barbara.

In its report, which was presented to the commission in September, the review groups said that it found the methodology used in the study—based on a fault-tree/event-tree form of analysis—to be basically sound. However it had a number of reservations about the way that the results of the analysis had been presented.

In particular, the committee criticised the narrow limits which the Rasmussen report had placed on estimates of the probability of a melt-down of the reactor core. The reasons for understating the error band, said the committee, included an inadequate data base, a poor statistical treatment, and an inconsistent propagation of uncertainties throughout the calculation.

The review committee also criticised the executive summary of the report—the part which has been most widely quoted in public discussions. The committee says that the summary did not sufficiently emphasise the uncertainties involved in calculating the probability of risk and that this might have led readers to a "misplaced confidence" in the validity of the risk estimated.

In a statement issued last week, the NRC commissioners say that they accept the criticisms of the review committee, and as a result have withdrawn any explicit or implicit endorsement of the report's executive summary.

On accident probabilities, the NRC says that the absolute values of risk in the Rasmussen report "should not be used uncritically either in the regulatory process or for public policy purposes". (The report states, for example, that nuclear power plants were about 10,000 times less likely to produce fatal accidents than man-made non-nuclear activities.)

The NRC's decision to support the Lewis Review Committee's findings has prompted the 65,000 strong Union of Concerned Scientists, which has been among Rasmussen's most vocal and persistent critics, to demand additional safety precautions at 16 plants where, they claim, there is evidence that the report was used to justify the acceptance of current safety procedures.

"Although the risks are still indeterminate, the uncertainty band includes an area of risk which is unacceptable, and it is on this basis that we are asking for the shutdowns", Dr Henry Kendall, Professor of Physics at Massachusetts Institute of Technology, said last week.

David Dickson

HSE confident it can cope

THE UK Health and Safety Executive (HSE) is confident that it is adequately staffed to inspect all UK laboratories doing genetic engineering experiments.

In reply to questions by the House of Commons Select Committee on Science and Technology last week, the HSE said that its three specialist inspectors for microbiological research could cope with inspecting the UK's seven Category Three and two Category Four laboratories. The time lag between notification of a laboratory's intent to conduct Category Three or Four experiments and inspection had never exceeded six weeks.

Laboratories conducting Category One and Two experiments do not need to be inspected before work can commence The HSE felt that because the inspection of these laboratories does not require such specialist knowledge, regional inspectors of medical laboratories could cope with them So far, about 200 experiments in 50 centres have been notified to the Genetic Manipulation Advisory Group (GMAG). Since last July the HSE and GMAG have jointly inspected 14 of the centres.

GMAG has recently had a change of membership Seven new members, J Chamberlain, Sir Frederick Dainton, J. Ingle, M Kogan, C. M Puxon, P. M. B. Walker and P. Wildy together with a new chairman Sir William Henderson started work in January Under its new chairmanship, GMAG may be taking a more positive attitude to work with recombinant DNA. Sir William has few fears about the potential scale-up of the processes in industry. He told the select committee at a previous meeting that "the hazards of scale-up are very much less than has been anticipated". He believes that 4,500 litres of reagent in clean, sealed stainless steel flasks are probably safer than the intermediate stage· "the danger is when you move from the bench to the 5 or 10 litre scale, when you don't have adequate procedures"

GMAG is setting up a subcommittee on scale-up, and Sir William is playing close attention to its membership He feels it should have a strong representation of chemical engineers who have experience of risk assessment in industry.

Dr Ken Duncan of the HSE shares Sir William's lack of fear about the dangers of scale-up to industrial processes when this happens, he says, the HSE will be able to call on its chemical engineers, currently engaged in other activities within the HSE, for advice Duncan, however, does not foresee unusual problems with scale-up. ☐

UK tightens up on lab safety

MANY OF the recommendations of the Shooter report, which called for tighter laboratory safety regulations following the smallpox outbreak at Birmingham University, are now to be implemented by the Government The move follows the unofficial "leaking" of the report by Clive Jenkins, general secretary of the Association of Scientific, Technical and Managerial Staffs. The Government's decision reveals that it no longer considers the country's voluntary safeguards for handling viruses in laboratories as adequate.

Social Services Secretary David Ennals told the House of Commons last week that several changes were to be made These include:

- Regulations compelling laboratories to give notice of their proposed work.
- An official licensing system to replace the present voluntary method of approving category A pathogen laboratories
- Accepting the recommendation that category A laboratories should be inspected annually.
- Setting-up a review of the Dangerous Pathogens Advisory Group, the body responsible for approving these laboratories, to find ways of broadening its membership to include wider union and public interest

No new legislation will be introduced to carry out these measures, which will be implemented as part of the Health and Safety at Work Act. Mr Ennals said public fears following the smallpox outbreak that killed medical photographer Janet Parker last September should not be allowed to cause panic If overprotective measures were introduced, there could be great damage to the ability to carry out effective diagnosis or research.

Mr Ennals also revealed that a reinspection of existing category A pathogen laboratories—which handle smallpox, rabies, lassa fever and other dangerous viruses—is now being carried out by the Health and Safety Executive. "In some cases it has become clear that improvements in safety procedures are necessary and immediate action has been taken", he said.

Details of these cases of "immediate action" were revealed by the HSE last week and consisted of stopping work with category A pathogens at two laboratories. The first, the public health laboratory at Colindale, North London, the only centre for rabies diagnosis in Britain, was visited on January 18 by HSE inspectors and a request for an end to dangerous virus work was issued

The order was made in the form of a Crown notice, which is not legally enforceable as one Government body cannot prosecute another, although the HSE has recently called Mr Ennals to remove Crown immunity for such laboratories. However, the director of Colindale, Dr Eric Mitchell, said a new purpose-built virus laboratoriy was to be opened there in a few weeks—after it had been inspected by the HSE, DPAG and the Home Office.

The other laboratory, at the Lister Institution in Elstree, Hertfordshire, has been asked to improve safety precautions in the production of rabies vaccines The laboratory was closed by the institution last June, and the HSE has instructed that it must not re-open without its approval.

Robin McKie

Switzerland to consider revised guidelines

Two months ago Mrs Shirley Williams, Secretary of State for Education and Science speaking on the television programme *Weekend World*, said that she would like to see the establishment of some form of international guidelines to regulate research on recombinant DNA Commenting on the different guidelines already in operation in the United States, Britain and the European Community, Mrs Williams singled out Switzerland as one country operating outside these formal rules. There was a need, she said, to induce it to come within some form of "containment barrier".

Switzerland is of course the home of the large multinational pharmaceutical companies F Hoffmann–La Roche, Sandoz and Ciba-Geigy. Roche and Ciba are both aware of the commercial possibilities of genetic engineering—and both have a finger in the pie Roche sponsors the Basle Institute for Immunology and Ciba the Friedrich Miescher Institute, also in Basle Both institutes have begun recombinant DNA research which is, as yet of a fundamental, rather than an applied nature.

But all recombinant DNA research in Switzerland whether commercially, privately or publicly sponsored is subject to certain controls The controlling agency is a commission set up by the Swiss Academy of Medical Sciences in 1975 In an open letter dated April 1978, the commission set out its control policy. It was the commission's view that the U S National Institutes of Health (NIH) guidelines should operate in Switzerland and it recommended this to all practitioners in the field. The commission also made it clear that the responsibility for the safety of this work lies with the principal investigator.

Professor Werner Arber of the Biozentrum at the University of Basle, and one of the 1978 Nobel Laureates in Medicine is a member of the commission. Commenting on the responsibility of the investigator, he told *Nature* that. "It is perhaps important to say that the Swiss Law of Epidemics foresees that any work with pathogens and their products has to be carried out with the maximum of care, and our commission interprets this formulation in such a way that recombinant DNA [research] done in our country has also to be done with a maximum of care".

The commission compiles an annual register of all work done in genetic engineering. In 1978 there were some 31 projects in the field under 18 principal investigators, eight of whom were based in Basle. The projects are divided into two groups according to their source of DNA for recombination. Category 'a' experiments are those using cellular DNA and using *E coli* as host; and category 'b' includes those using DNA from plasmids, bacteriophage and viruses and again using *E coli* as the host. Twenty-two of the projects are in category 'a' and include work with embryological tissue from primates, other mammals, birds and cold blooded vertebrates. Eight of the 'a' category are listed as using 'inferior eukaryotes' as a source of DNA. In category 'b' the recombination work is listed as involving plant viruses, 99% pure organelle DNA from eukaryotes (but not primates) and plasmids or phage DNA from hosts, the genes of which are interchangeable with *E. coli*.

Of the 18 principal investigators 15 are based in universities, with the remaining three privately sponsored.

It is the European Science Foundation (ESF) which is trying to harmonise the guidelines and working conditions in recombinant DNA research in Europe. Arber represents the Swiss Commission at the ESF meetings and appreciates the effort the Foundation is making to find the common ground. However, Arber says that the Swiss Commission has still not reached a firm decision on the guidelines it will adopt in the future. In the next few months the commission will meet again to consider the revised NIH guidelines (which lift restrictions on some categories of recombinant DNA research, but which for the first time extend the controls to cover industry), those of the UK Genetic Manipulation Advisory Group, and the guidelines proposed for France and Germany.

Alastair Hay

Catch a falling Kosmos—and send the bill to Moscow

OPERATION Morninglight—the clean-up of northern Canada, following the "unscheduled re-entry" and crash of the Soviet satellite Kosmos-954 a year ago is now over, at a cost of some $13 million. Canada is sending a bill for $6 million to the Soviet Union.

Kosmos-954, which carried a power-source fuelled with some 50 kg of enriched uranium, crashed in the area of the Great Slave Lake on 24 January 1978. The first stage of Morninglight was launched within hours—a massive air search for radiation hot-spots. Within four days, three radiation hot-spots were located, and several more within the next week.

A party of six meteorologists encamped in the Warden's Grove area, two of whom actually touched a fallen fragment, were evacuated to Edmonton for radiation tests; but they showed no signs of contamination. As for the local Chipewyan Indian population, apart from a missing pair of trappers who were feared to be camping near a hot-spot, the greatest danger seemed to be fear and bewilderment as to the nature of the search, plus the ominous appearance, in the settlement at Snowdrift, of a wolf which refused to be driven away and finally had to be shot.

The second stage of Morninglight—a ground level survey—was scheduled for July, when the snows had melted. Shortly before it was to begin, uranium prospectors reported satellite debris in northern Saskatchewan, and the search was extended beyond the Great Slave Lake area. Morninglight finally covered some 90,000 square kilometres, from which over 3,000 pieces were recovered, mostly small particles, but with a few larger fragments, one of which was said to be—"as big as a five gallon drum". One of the larger pieces was so radioactive that a special lead container had to be built by the University of Alberta. Another fragment, though, a 225 cm × 50 cm stove-pipe shaped cylinder, was sufficiently "cool" to be loaned for temporary exhibition to the National Museum of Science and Technology in Ottawa.

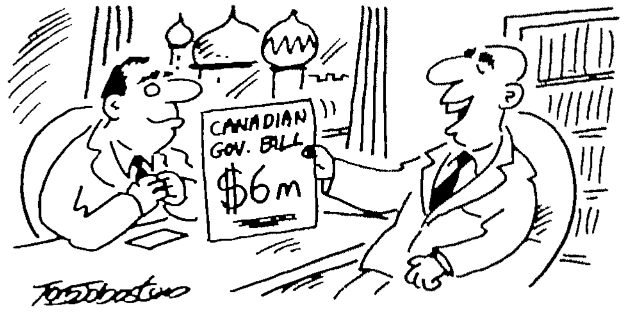
By the beginning of winter, when phase two of Morninglight ended, the Atomic Energy Board of Canada announced that the residual radiation risk in the impact area was minimal. Any remaining radioactive debris would soon decay to below natural background level, and the hazard to humans or wild life from accidentally ingested particles would be no greater than that from a medical x-ray examination. Nevertheless, as an additional precaution, the Federal Environment Department would monitor fish from the Great Slave Lake, while the Health Department would check the meat of migrating caribou herds.

Apart from these minor hazards, and the $13 million bill, what are the lasting effects of the Kosmos-954 incident? First, the setting up, on Canada's initiative, of a UN working group to study the technical aspects and safeguards for nuclear power sources in space, the first meeting of which will take place later this year. Minor spin-offs include a considerable amount of practice in the aerial and ground location of radioactive debris, and the (at least temporary) appearance on the map of the name "Cosmos Lake" to denote the base camp of the aerial search.

Canada's claim against the Soviet Union will doubtless provide international lawyers with fascinating material on compensation norms and procedures. As far as the average Canadian is concerned, there remains a profound sense of thankfulness that the impact took place in a virtually uninhabited area—and considerable apprehension of what could happen next time.

According to NASA officials, there is a 2% chance of debris from Skylab striking Canada. Moreover, any such impact would occur south of latitude 50°N—a band which includes all major Canadian cities except Edmonton and Calgary. Not surprisingly, Canadians are said to find the news of the forthcoming descent of Skylab to be, at the mildest, "somewhat disturbing".

Vera Rich



"There's a fair chance that the Skylab crash will wipe out all record of this bill, comrade!"

news in brief

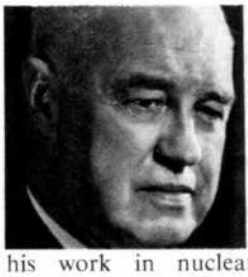
ASTMS branch wins redundancy rights: A local branch of the Association of Scientific Technical and Managerial Staffs has persuaded the Royal Free Hospital School of Medicine to withdraw waiver clauses concerning redundancy rights from its fixed term contracts. The school secretary, Mr G. W. Fenn, refused the initial ASTMS request. Negotiations were then referred to the school's joint negotiating committee, composed of three ASTMS representatives and three administration representatives. They also rejected the proposal but after discussion agreed to present the request to the full school council (from which ASTMS representatives are excluded). The council agreed to withdraw the part of the waiver clause requiring employees on fixed term contracts to give up their rights to redundancy pay but have retained the waiver for rights against unfair dismissal. "To maintain happy relations in a small organisation like ours, we felt it was a good thing to do for the employees," said Fenn.

UNEP calls key meeting on Mediterranean pollution: The United Nations Environmental Programme is convening a meeting of the Mediterranean Action Programme from 5–10 February to discuss the activities of the 1979–1980 MAP programme, the location of MAP headquarters and most important, the share out of \$2¼ million operating expenses among the 17 member states. Some struggle is expected about the exact terms of the share out but the conference is expected to make slow steady progress towards the eventual goal of a full Mediterranean clean-up. The major problem, towards which the conference will make a small contribution, is land-based pollution—industrial water, domestic sewage, agricultural pesticides and fertilisers—which account for 85% of Mediterranean pollution. The World Health Organisation estimates that it will cost \$5 billion over a period of 10 to 20 years to control pollution at the source, often hundreds of kilometres upstream from the Mediterranean.

US prepares for Skylab re-entry: The US government has set up an interagency group to prepare for possible damage when Skylab re-enters the earth's atmosphere later this year, Dr Robert Frosch, administrator of the National Aeronautics and Space Administration, told a Senate panel last week. The State Department, the Department of Defense and the New Federal Emergency Management Agency are working with NASA to set up an international warning system and an assistance team to deal with any damage or injury caused by debris from the 80-ton space station as it re-enters the atmosphere.

Dr Frosch told the Senate subcommittee on space and science: "There are potential options of exerting some influence on what happens to Skylab during its last couple of orbits." But, he said, NASA scientists did not yet know how much control they would have over Skylab's break-up —and in particular whether they could bring it down over an ocean. One critical factor was the power supply, and whether Skylab's solar panels could be kept fully charged. If Skylab could not be reliably brought down into the sea, it might be wise not to try to influence its descent, Dr Frosch suggested, because of the political implication of the US trying to crash the debris into a particular part of the globe.

Sullom Voe oil spill: Census taken by the Royal Society for the Protection of Birds after the Shetland Island oil spill, where 1,150 tonnes of heavy bunker fuel oil fouled fifteen miles of coastline has shown the spill to be "locally disastrous" according to Bobby Tulloch, RSPB representative. 2,800 birds from 45 species have been killed. Of the local eider population of 350 birds, 5 are left, with a similar picture extending to other species. Twenty others have been killed or "badly affected" and it is not clear whether any remain. Local sheep that graze on seaweed deposited along the rocky coast have become polluted with unknown toxic and carcinogenic effects.



Soviet award for Todd: The Lomonosov medals, the highest awards of the Soviet Academy of Sciences, are awarded each year to one Soviet and one foreign scientist. The 1978 awards, announced last week, go to Academician Anatolii P. Aleksandrov, president of the Soviet Academy of Sciences, for his work in nuclear physics, and Lord Todd (left), president of the Royal Society, for his work in biology. The linking of the two Presidents in this way is something of an auspicious coincidence. The Royal Society has a long standing scientific exchange programme with the Soviet Academy, dating back to 1956 and the very beginning of the post-Stalin "thaw". The then Dr Alexander Todd helped establish this exchange.

British students swing to science: Statistics from the two major school examination boards in Britain are showing a trend back towards physical sciences at A-level, at the expense of subjects like history and geography. Recovery from the slump in interest of the mid-1970s is particularly apparent in chemistry, where the number of candidates entering the London Schools Examination Board A-level has increased from 14% to 16% in the last four years, while the Joint Matriculation Board's chemistry candidates accounted for 21.3% of total entries, the highest proportion since their comparative statistics began in 1971. Physics and mathematics are following the same trend, with increases of around 1% to 2% over the past two to three years. With a total A-level entry to these boards of 66,000 and 55,000 respectively in 1978, even a small percentage increase indicates a significant swing towards science.

However, Professor L. A. B. Elton of the Institute for Educational Technology, Surrey University, considers the statistics as presented are "too bland for anyone to draw sensible conclusions". They do not distinguish between male and female candidates, for example.

Seasat failure due to technical and management faults: The failure of the Seasat satellite, which was launched early last year by NASA and which ceased transmitting data in October, was the result of a "massive and progressive" short circuit, due to a "lack of proper attention" by NASA's jet propulsion laboratory and the Lockheed Missile and Space Company to testing of the rocket stage to which the satellite was attached. "As a result, a test was waived without proper approval, important component failures were not reported to project management, and flight controllers were inadequately prepared for their task," said a board of enquiry in a report issued last week.

Seasat was launched to test equipment for gathering data on the world's oceans for both scientific and meteorological purposes. Before the failure occurred the satellite had been transmitting data for 99 days. The report says that the most likely cause was an electrical arc between adjacent slip ring brush assemblies.

Correction: President Carter has requested a budget increase for basic science of 2% above inflation, not 20% as reported on page 252 last week. . . . alas.

Does the UK have a numeracy problem?

Joseph Schwartz puts his own view of the controversy over the mathematical abilities of UK schoolchildren

IN March 1978 Dame Kathleen Ollerenshaw, President of the Institute of Mathematics, released her account of innumeracy in Great Britain to the press. "Simple sums floor vast majority of pupils" was the *Times* headline. An examination administered to 7,000 15-year-olds in six education districts produced "abysmal" results.

The test consisted of 17 questions, of which nine had two parts and two had three parts, requiring a total of 44 basic operations to be performed in 40 minutes. The problems ranged from 12 computations of the type $14+35=?$ to nine word problems (How much do I save if I buy two large bottles of shampoo (150 cc @ 25p) instead of taking the same quantity in small bottles (75 cc @ 15p)?) and included questions involving the reading of graphs and train timetables.

Calling a mark of 90% adequate and a score of 80% well below an acceptable standard, Institute members were disappointed in the actual results. The percentage of pupils receiving an 80% score in the six districts ranged from 21% to 61%. The percentage of perfect papers ranged from 1% to 13%. Dame Kathleen said "education as a whole, and parents and employers will agree, is not doing a good enough job".

More recently, in September 1978, the Department of Education and Science announced the formation of a Committee of Inquiry into the teaching of mathematics in schools. This new committee is a consequence of the 1976-1977 Tenth Report of the Expenditure Committee on the Attainments of the School Leaver in which mathematics was particularly singled out for attention. "We heard more statements about mathematical competence or lack of it than about any other school subject. The CBI described it as the issue most frequently mentioned by their members".

Dr H R Pitt, a mathematician and now Vice-Chancellor of Reading University, testified "I think there is no doubt that there is something of a crisis in the teaching of mathematics", attributing the crisis to the introduction of "a lot" of new methods, too rapid change of curriculum and a shortage of skilled teachers. The terms of reference of the Committee of Inquiry are: "To consider the teaching of mathematics in primary and secondary schools in England and Wales with particular regard to the mathematics required in further and higher education, employment and adult life generally and to make recommendations".

But workers in the field of numeracy and maths instruction greet these developments unenthusiastically. Jo Stephens of the DES Mathematics Inspectorate points to some historical antecedents of the present upsurge of interest in mathematics.

In 1954 the Mathematical Association reported: "The standard of mathematical ability of entrants to the Trade Courses is often very low".

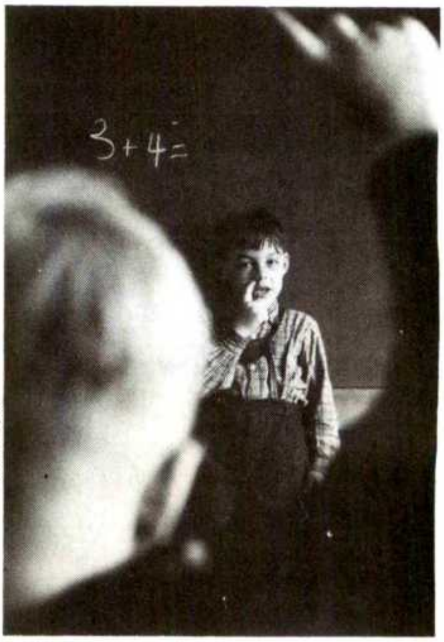
In 1925, the Board of Education reported: "It has been said that accuracy in the manipulation of figures does not reach the same standard which was reached 20 years ago. Some employers express surprise and concern at the inability of young persons to perform simple operations involved in business".

In 1912 an LCC report noted: "There is a prevailing opinion that London elementary school children of today are slower and less accurate in computation than they were ten years ago". And in 1876 the Mathematics Inspector reported: "In arithmetic I regret to say worse results than ever before have been obtained—this is partly attributable no doubt to my having framed my sums as to require more intelligence than before . . .".

The problem, then, is not a new one. Seen in this light the current focus on numeracy is simply a political football to be pursued by the media and government as it suits them.

Blanket blame of teachers, attacks on mixed ability classes and an abstract concern with 'standards' characterise the debate so far. Some members of the Expenditure Committee are alive to the fact that a person's numerical skills bear little relationship to the requirements of the available jobs. "Unqualified school leavers competing for the diminishing pool of jobs at below craft level find that they lose out to the qualified school leaver who is eager to take a job below his (sic) capability rather than be unemployed".

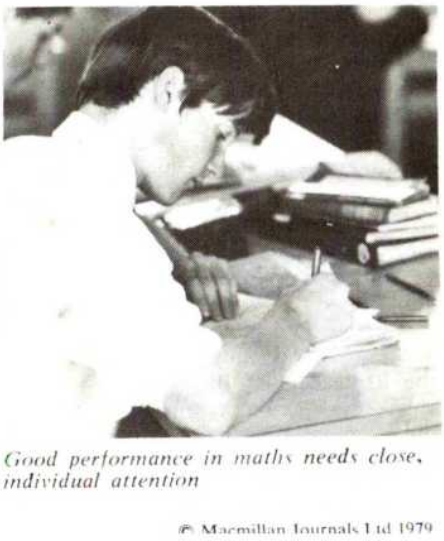
In other words, in a buyer's market, employers are selecting the qualified school leaver for jobs that would normally go to the unqualified leaver. The unemployment problem is not due to a lack of competence of the workforce. Making people more numerate may help them to compete more effectively but it will not increase the number of jobs. To imply that it will, however indirectly, is to make a scapegoat out of the schools.



Barnaby's

Nevertheless, Dame Kathleen's report does indicate that there is room for improvement in the mathematical abilities of school leavers. Where *does* the problem lie? The teachers themselves should surely know best.

Most numeracy teaching is based in fifteen Colleges of Further and Higher Education in the London area. The problems presented to teachers are extremely varied—as are the students. A major facet is that the problems of numeracy and literacy are intertwined. There are very few people who can work with numbers without being able to read and as such many numeracy problems are handled within the much larger literacy programmes. The majority of remaining students are young adults who either have been referred to numeracy courses from programmes like Manpower Services Commission's Training Opportunities Scheme or who feel the need to improve their computation skills for various courses ranging



Barnaby's

Good performance in maths needs close, individual attention

0028–0836/79/0273—0344$01.00

from craft apprenticeships to office work.

Linda Major, an Advisory Teacher in numeracy based at Westminster College, says that students generally have little trouble with addition but do have certain problems with other operations. Frequently, she says, students will be able to use subtraction in the act of handling money but will have difficulty in working it out on paper. Major feels that some part of the traditional curriculum such as long division and fractions are of little practical use in adult life and makes no attempt to teach this.

Relevance is crucial to the approach. The students are riveted when it comes to the question of tipping but it is another matter when percentages are taught. (Literacy methods are similar. Jud Stone of City and East London College uses materials created by the students themselves. Instead of reading texts of little immediacy students learn to read their own words. The method places far more emphasis on writing than reading.) Major says that the goal of fluent single digit addition and multiplication along with a knowledge of how to compute with larger numbers using the ordinary place value algorithm is attained when there is adequate staffing.

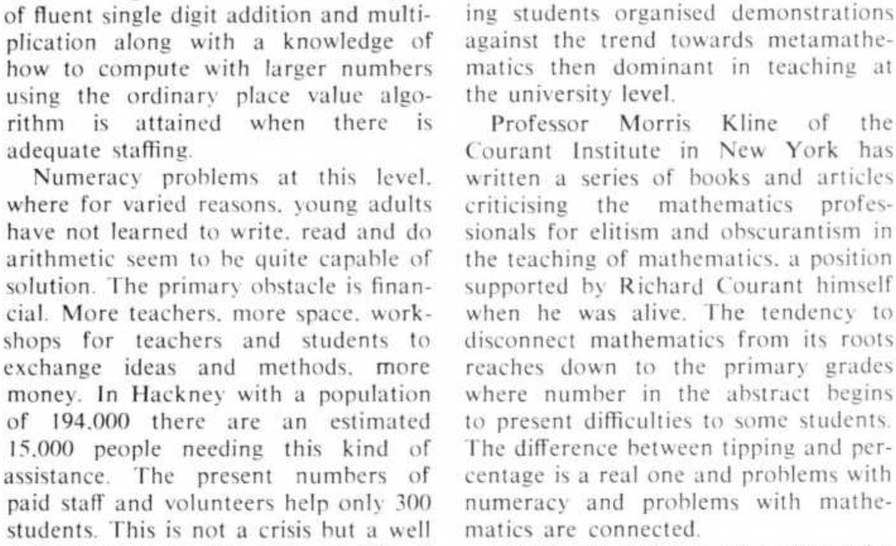
Numeracy problems at this level, where for varied reasons, young adults have not learned to write, read and do arithmetic seem to be quite capable of solution. The primary obstacle is financial. More teachers, more space, workshops for teachers and students to exchange ideas and methods, more money. In Hackney with a population of 194,000 there are an estimated 15,000 people needing this kind of assistance. The present numbers of paid staff and volunteers help only 300 students. This is not a crisis but a well defined need on the part of 8% of the population of Hackney. Current expenditure is too low. The Adult Literacy Support Services promises some additional volunteer assistance but it is doubtful that without proper training, proper space, proper materials, in short, proper organisation, that such an intervention can be effective. Some workers question the wisdom of basing a programme on unpaid labour but in the current situation they are not going to refuse help in any form.

At a higher level, more fundamental questions can be raised. University graduates in general and scientists in particular have all experienced difficulties when confronted with mathematics. According to Emilio Segrè, Enrico Fermi attended a conference at Bohr's institute on the weak interactions. At the end of two hours of symbols the lecturer concluded, "And that is Fermi's theory of the weak interaction". Said Fermi, "It was the only part of the lecture I understood".

Mathematics has had in its history a long dishonourable thread of mystification and inaccessibility going back to Plato. The most militant opposition to this tendency that I know occurred in Germany in the 1890s where engineering students organised demonstrations against the trend towards metamathematics then dominant in teaching at the university level.

Professor Morris Kline of the Courant Institute in New York has written a series of books and articles criticising the mathematics professionals for elitism and obscurantism in the teaching of mathematics, a position supported by Richard Courant himself when he was alive. The tendency to disconnect mathematics from its roots reaches down to the primary grades where number in the abstract begins to present difficulties to some students. The difference between tipping and percentage is a real one and problems with numeracy and problems with mathematics are connected.

Additional criticism of mathematics along these lines is starting to come out of the analyses of sex differences in educational achievement. Alison Kelly, a lecturer in sociology at Manchester University says that as well as social pressures in all their forms that are exerted on girls to avoid science and maths there is the problem of the stereotypical image of science and maths itself—cold, remote and abstract.



Teaching relevancy at an early age

Anthea Sieveking

Kelly and other analysts assert that women's rejection of mathematics is far more active than the usual portrayal of women as passive victims of a social role. "Women reject mathematics and the sciences as military and industrial activities bearing no relationship to helping activities or being able to explain oneself to oneself". If this is true of large numbers of women it is interesting to speculate on the possible effects of a major government effort to recruit more women to engineering, maths and science.

A different approach to the well-educated person's problems with mathematics was tried last year by Larry Buxton of the DES Maths Inspectorate. Recognising that there were important emotional responses to mathematics Buxton attempted to deal with these directly using the methods of psychotherapy He worked with a group of six adults for 24 sessions and with three individuals for 12, 24 and 36 sessions respectively.

On the basis of the experience Buxton is convinced that the central problem is as much emotional as cognitive. "The exploration of emotion is not supposed to be related to in mathematics yet it is the subject with the most charged emotional content". Numeracy teachers deal routinely with problems on this level although it seems unlikely that widespread intervention based on individual counselling is feasible. But Buxton thinks that two widely accepted practices in mathematics instruction are open to question.

The first is the use of timed tests. The present curriculum confuses the need to work hard with the need to work fast, he says. Good performance in mathematics needs close, concentrated undivided attention and students must not feel rushed. The second practice involves complex attitudes towards authority. An interrogative approach in the classroom based on categorical right or wrong answers can be threatening and off putting to many students. This combination of time and authority was a recurring theme for the people with whom Buxton worked.

So there are many directions in which the teaching of mathematics can be improved. But a barnstorming attitude based on the false perception of a 'crisis' and on weak analysis of the problem is going to achieve very little. If the government wishes to improve the mathematical level of its schoolchildren it could do a lot worse than to listen to those teachers most directly confronted with the problem. □

GMAG should look to NIH

SIR,—I write to enquire whatever happened to the public debate on changes in the regulations for genetic manipulation experiments? The notion of rationalising genetic manipulation containment by measuring the risk in each experiment was put forward in the columns of *Nature* last month. A public meeting was promised and was indeed convened in London on 21 December. This meeting could be called neither public nor a debate and achieved little or nothing. Views were expressed by members of GMAG, both on the panel and in the audience, that revealed strong political polarisation but little in the way of scientific evidence supporting either the present guidelines or possible alternatives. From the body of the meeting the only view which came across strongly and repeatedly was the indignation of many scientists at the classification of experiments involving the manipulation of *E. coli* DNA in *E. coli*. A host of important questions concerning the proposed new systems of evaluating the necessary containment for particular genetic manipulation experiments were not raised at this meeting. Even where one or two points were raised, time for discussion was inadequate. It is safe to conclude that there has been no proper forum for public debate.

By contrast to events in this country we have the example of the way in which the NIH guidelines have recently been revised in the US. Irrespective of whether one agrees or disagrees with the new NIH guidelines one must admire the broadly based public debate, the informed political comment and the rapidity of the process of modification of the proposals in response to debate and comment. Moreover the whole process, up to and including publication of the new guidelines, is freely available in the Federal Register. We could, to our advantage, learn from those events.

The need to change the genetic manipulation guidelines in Britain is just as pressing as was the need in the US. Our present guidelines are illogically restrictive. The levels of containment imposed upon genetic manipulation experiments in Britain have from the beginning exceeded those required in the US. This difference taken together with the lack of availability of physical containment facilities in this country has meant a severe handicap for British work with systems designated as requiring high containment. The introduction of the new NIH guidelines has widened the gap between containment required in the US and that required in Britain to such an extent that it is now impractical to continue a wide range of genetic manipulation experiments in this country. On a global basis it perhaps matters not whether Britain is involved in genetic manipulation research. For Britain however, the consequences of missing out on a revolution in biological technology and in losing a generation of the best young scientists who wish to be trained in that area will be dire.

If the guidelines for genetic manipulation experiments in Britain are to be changed then the change must be effected rapidly. There is no sign of swift action on the Brenner initiative nor of an informed debate. Looking again at the global picture, should we be so insular as to think that we should repeat a process which has been painstakingly conducted in the US. Biological risks by their very nature do not respect national boundaries. We would be wise to look carefully at the guidelines accepted by the majority of scientists working with genetic manipulation and by the nation within which they carry out their work. I think that we could, without endangering either workers in the field or the public at large, adopt the philosophy of the NIH guidelines and indeed, with certain modifications to British conditions, the letter of those guidelines. The NIH guidelines remain largely empirical but they are based on extensive experience. In science we do not look at national origins in evaluating ideas or experimental results. I trust that in this case that neither national pride nor political ideology will prevent serious consideration of the NIH guidelines as a suitable model for genetic manipulation work in Britain.

Yours faithfully,

ALAN R. WILLIAMSON

Institute of Biochemistry,
University of Glasgow, UK.

The status of safety officers

SIR,—In your editorial "Smallpox: ignorance is never bliss" (11 January, page 75), you advocate a new breed of medically qualified safety officers, universally respected. Whilst I agree that a properly professional approach to laboratory safety is required, I suggest it would be inappropriate to require medical qualifications for safety officers.

Your suggestion that "a safety officer should always be a doctor" is ill considered. The example upon which you seem to have based the proposal is misleading. Dr Mark Darlow was in a unique position at MRE Porton. He was successful because he was the right person for that particular job.

There has been a predictable reaction in the press to the whole sad saga of Birmingham. We must use the impetus of public concern to improve our scientific safety position. It is undeniable that our scientific safety has left much to be desired and that many of its practitioners have been ineffectual. We should introduce a system for recognition of professional safety officers combined with a worthwhile career structure to encourage people in whom both the general public and the scientific community can feel confident.

The status of safety officers should be assured by their employers—who are ultimately responsible for safety under the Health and Safety at Work Act (1974). Safety officers are charged with obligations to ensure the observance of statutory regulations and safety codes. They should work in conjunction with a safety committee constituted to represent all groups of employees from academic staff to ancillary staff.

Thus it will only be when properly qualified and professionally accountable safety officers are employed and given the opportunity and incentive to carry out research and to get on with the job of safety in science, that we could feel that we have learned the lessons so apparent in this latest tragedy.

Yours faithfully,

M. R. BAILEY

National Institute for Medical Research,
London, UK.

Reason not ruction

SIR,—In your issue of 21/28 December, page 753, Dr Kenneth Mellanby quotes a secular hymn from a Socialist Sunday School in Glasgow in the 1920s:

"By nature not nurture we'll rise to the skies
The means of production we'll nationalise."

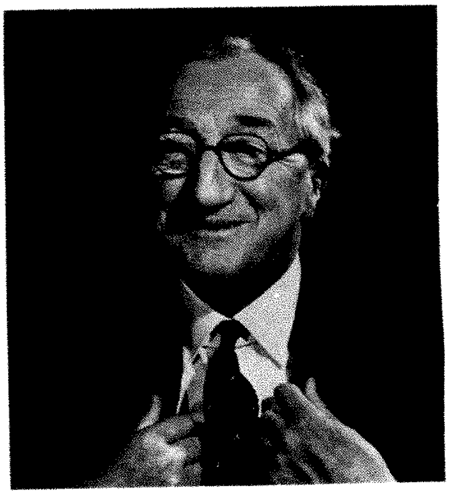
This is curiously like the refrain from a revue song by A. P. Herbert, which I quote from memory:

"By reason not ruction we'll soar to the skies
The means of production we'll nationalise
And rapture surprising we'll bring within range
By nationalising the means of exchange."

I prefer APH's version.

Yours faithfully,

O. MAYO



A. P. Herbert: British humourist

news and views

Periodical cicadas

from Robert M. May

In 1970, Princeton University conferred an honorary degree on Bob Dylan. The graduation ceremony coincided with the local emergence of periodical cicadas, which appear in vast numbers every 17 years, and the air was dense with their bodies and their song. Dylan recorded the occasion ('Day of the Locust' on *New Morning*, Columbia PC-30290):

These cicadas (not locusts; Dylan's honorary degree was in Letters not Science) are a unique biological phenomenon. They comprise three species in the genus *Magicicada*, and have the longest life cycle known for any insect. Found throughout the eastern United States, the nymphs live 6 to 24 inches below the ground, where they suck juices from the roots of forest trees. Mature nymphs emerge, assume their familiar adult form, mate, lay eggs and die within the same few weeks of every seventeenth (in the north) or every thirteenth (in the south) year. The synchrony is astonishing: although different 'broods' in different regions may be out of synchrony by several years, in any one population essentially all the animals are the same age, and the three different species are invariably synchronised whenever they coexist (as they commonly do). As far as anyone has been able to tell by conventional taxonomy or by the song of the males, each of the three species exists with both a 17-year and 13-year life cycle.

The difficult questions that are posed by the existence of these remarkable creatures are lucidly set out in the classic papers of Lloyd and Dybas (*Evolution* **20**, 133; 466; 1966) There are two basic problems. First, how did such a cycle, with so long a period, originally evolve? Second, how is the clear-cut periodicity and the synchrony between co-occurring species maintained?

The second question is more easily answered than the first. Given that there already is a long life cycle and a nearly-perfect periodicity of emergence, the cicadas can effectively escape predation. Above-ground predators such as birds, who have no analogous resource in the long intervals, are satiated, and below-ground predators, such as moles, are unexpectedly deprived of food by every periodical emergence. The resulting population densities achieved by periodical cicadas are one or two orders of magnitude greater than those of their more stodgy relatives that appear each year. Lloyd and Dybas estimate that the nymphs may typically attain densities of one ton per acre. The selective pressures are for doing well at high population densities, even at the cost of being conspicuous and sluggish ('predator-foolhardy' is Lloyd and Dybas' term). Any mutant, migrant or developmentally different individual who fails to emerge with the majority will almost certainly be snapped up by predators. Lloyd and Dybas review observations and experiments bearing this out: typically the cicadas that emerge during the first few days are all eaten by birds; in 1889 Marlatt transported large quantities of eggs to an area where the adults that emerged in 1906 were out of phase, and the entire colony of more than 10,000 individuals was effortlessly consumed by grackles In brief, the long-period cycle enables the cicadas to saturate their predators, which reciprocally helps to stabilise the cycle as individuals appearing earlier or later are gobbled up

This conspicuous association between predation and periodical behaviour has led many people to speculate that the magic numbers 13 and 17 arise because they are prime, thus preventing any possible subharmonic resonances by the predators. Robert MacArthur remarked that it may be the only application of number theory, as such, in mathematical biology I am surprised nobody has yet suggested that the prime number 11 is missing because it permits resonances with the sunspot cycle!

Two recent papers have developed some of these notions more formally, providing useful insights.

Hoppensteadt and Keller (*Science* **194**, 335; 1976) present a mathematical study whose essentials are simple. The cicadas have a life cycle of length L years. All 'broods' may be present, that is, the periodical emergence is not assumed. Each year the nymphs in the appropriate brood emerge and become adult, with each surviving adult producing an average of f offspring. Nymphs belonging to the other broods suffer some mortality, with a proportion α surviving into the next year. The newly hatched nymphs become established underground, subject to the constraint that the total number of nymphs present in the ground in any one year is limited to be not more than some carrying capacity K. Finally, the adults suffer predation, up to a saturation level that depends on the predator density if the number of cicadas is below this saturation level, all are eaten; if above, the excess survive to reproduce. The predator density depends on the previous year's density (reduced by a mortality factor R) and on the previous year's recruitment (proportional to the number of cicadas consumed that year) This dynamic model of the interaction between cicadas and their predators can have three distinct outcomes If predation is too severe, the cicadas cannot survive, and the system collapses. If predation is relatively unimportant, a 'balanced' equilibrium in which a constant number of cicadas emerge each year is possible, and seems to be the only stable state. Most interesting is the case where predation is of an intermediate strength, such that a balanced state is not possible, but a periodical state (with just one brood, emerging every L years) is possible. The criterion for this intermediate situation to hold is that

$$\left(\frac{AF}{1-F}\right) > 1-R > \left(\frac{AF}{F-1}\right)\frac{R^{L-1}(1-R)}{(1-R^{L})}$$

Here R and L are as defined above, $F=f\alpha^{L}$ is the average number of offspring produced, and A is the efficiency

---

Robert M. May is Class of 1877 Professor of Zoology at Princeton University.

at which consumed cicadas are converted into predator biomass. The mechanism underlying this intermediate case is not simply that the high cicada density associated with the periodical state saturates the predators while the balanced emergences cannot (remember that in this model higher cicada densities will generate higher predator densities), but rather that the longer periods between recruitment in the periodical state make it harder for the predators to keep their density high (hence the factor R^L on the right hand side of the equation). The above criterion is a rather delicate one to satisfy, and large values of L help to do so. Hoppensteadt and Keller arbitrarily choose parameter values which produce beguiling figures in which synchronised, periodical behaviour is manifested once the life cycle L exceeds 10 years, with balanced annual emergences for L less than this.

Hoppensteadt and Keller's model is valuable in showing how periodical behaviour can emerge as a stable phenomenon, provided that predation is of some intermediate intensity. The mechanism involves an explicit interplay between resource limitation (without which the system would either collapse or run away) and predation (without which the system would settle to a balanced state). The conclusions are not sensitive to Hoppensteadt and Keller's assumption about the dynamics of the predator population. If I replace their dynamically varying expression by a fixed predator population of magnitude P, the same three cases arise, with the interesting intermediate situation pertaining if

$$\left(\frac{1-\alpha^L}{1-\alpha}\right)\left(\frac{F}{F-1}\right) > \frac{K\alpha^L}{P} > \left(\frac{F}{F-1}\right)$$

This expression has the same general character as Hoppensteadt and Keller's. In reality, the predator population is neither entirely independent of the cicadas, nor entirely dependent on them. It is therefore reassuring that the essentials of this mechanism for producing synchronised, periodical emergences are independent of the details.

Bulmer's (*Am. Nat.* **111**, 1099; 1977) study pays more attention to competition among the nymphs under the ground. Motivated by the suggestion that periodical emergences can be produced by competition that is more severe between than within year-classes, Bulmer considers a mathematical model without predators. He finds balanced solutions if competition is fairly uniform, and periodical solutions if inter-brood competition significantly exceeds intra-brood. When the effects of predation are added (assuming a constant predator population), a conclusion similar to that of Hoppensteadt and Keller is reached: low levels of predation leave the balanced solution stable, but intermediate levels destabilise the balanced solution and produce a periodical one. In his discussion, Bulmer flouts the conventional wisdom, concluding that "competition between year-classes is the main factor likely to lead to periodical behaviour". This conclusion, however, depends crucially on whether inter-brood competition is indeed a lot more severe than intra-brood (as Bulmer assumes) or not (as Hoppensteadt and Keller assume). The facts surveyed by Lloyd and Dybas seem to me to speak for the later view: the fighting behaviour displayed by nymphs in defence of their cells suggests competition is significant; but there is great variability in size among nymphs of the same age ("the range of variation within a year is far greater than the mean difference between years", Lloyd and Dybas, *op. cit.*, page 473) which makes it unlikely that inter and intra-brood competitive interaction are greatly different.

Bulmer also considers the situation when two or three species of periodical cicada occur together, and shows that satiation of predators is a most effective mechanism for synchronising the emergences. He also compares his mathematical studies with information about the natural history of some other periodical insects, namely May beetles (which over most of their range are periodical with a 3-year life cycle, lengthening to 4 or 5 years in some regions of northern Europe) and the northern oak eggar (which has periodical behaviour with a 2-year cycle). Although these insects have much shorter cycle times, and less dramatic population behaviour, than the *Magicicada* species, Bulmer's idea of using them to help shed light on the evolution and maintenance of periodical behaviour is a nice one.

The studies by Hoppensteadt and Keller and by Bulmer both assume that the periodical cicada populations are limited by the resources available to the nymphs. Lloyd and Dybas contest this point. They suggest that more nymphs could usually be sustained in their environment, and that the overall population is limited by a fungus disease, *Massospora cicadina*, which afflicts adult cicadas; the resting spores of this fungus survive for decades, and thus amount to a form of 'predator' for whom 17 years is a short time. If Lloyd and Dybas' speculation is eventually borne out, it will constitute a striking example of the magnitude of a natural population being ultimately controlled by a disease (Anderson & May *J. Anim. Ecol.* **47**, 219; 1978).

There remains the fundamental question of how the 13 or 17-year cycle first evolved. Lloyd and Dybas survey two classes of explanation.

One envisions a periodical pattern first appearing in order to facilitate predator saturation, and then gradually lengthening. The problem here is that the very same mechanisms that maintain the periodical behaviour would select against any deviant cicada that tried to add a year to its cycle time; a cycle in which predator satiation played a crucial role could conceivably evolve to be shorter, but not longer. On this basis, the periodical cicadas seem to be sitting on an 'adaptive peak' to which there is no accessible approach.

The other type of explanation assumes an initially 'balanced' cicada population, controlled by predators and parasitoids, all of whose cycle times lengthened, perhaps for developmental reasons or perhaps driven by an evolutionary race between prey and predator. Once the cycle time L attained in this way becomes long enough (in the sense specified by the equation above), the balanced configuration can abruptly become unstable and yield a periodical one. Moreover this discontinuous change in the dynamics of the system could spell extinction for some of the previously key parasitoids, thus making the situation observed today all the more enigmatic. This is pretty vague stuff, but there is at least some evidence that cycle times for insect prey and predators can be long. Other species of forest cicada for which the life cycles are known have 7-year cycles; long cycle times may well be common among cicadas with more or less 'balanced' behaviour. Among their predators, the large Australian cicada-hunting wasp, *Exeirus lateritius*, has facultative dormancy of 2 or 3 years, and some of the parasitoids of the wheat blossom midge, *Sitodiplosis mosellana* (which itself has a dormancy underground of up to 13 years), exhibit dormancy periods of up to 8 years. Recent work on models for host-parasitoid systems with mixed developmental periods for the hosts and with parasitoids whose cycles are submultiples of their hosts' (MacDonald *Math. Biosci.* **31**, 255; 1976; Beddington, Free & Lawton *Nature* **273**, 513; 1978) lay the foundations for a more quantitative exploration of these ideas.

Finally, a kind of experimental test between the above two general explanations is possible. On the first class of explanation, we would expect the 13-year cicadas to have appeared first, and the 17-year ones to have evolved from them. On the second class of explanation (which acknowledges that once periodical behaviour becomes established, cycle times can only evolve to be shorter), the 13-year cicadas would

0028-0836/79/0277-0348$01.00

be derived from the 17-year ones. White and Lloyd (*Am. Midl. Nat.* **94**, 127; 1975) have shown that the 13-year cicadas have five instars (the last of 4 years' duration), while the 17-year ones have an extra, sixth instar of 4 years' duration If the second explanation is correct, the 13-year cicadas evolved by dropping an instar, and they should be replacing the 17 year ones whenever they are in contact. Such regions of contiguity exist, for example, in the Ozark mountains, and detailed studies of future emergences in this region will be interesting. This touches on a practical problem in this research, namely that, whatever their significance in the world of pedators and parasitoids, 13 and 17 years are much longer than the time scale for most research grants and tenure decisions.

To summarise, it is hard to see how periodical behaviour can evolve. In particular, the Hoppensteadt-Keller criterion can only be satisfied by a delicate juggling of the pertinent parameters. But it should be remembered that the periodical cicadas comprise only 3 of some 1,500 cicada species; an easy explanation for the phenomenon would be an embarrassment! ☐

Testing quantum chromodynamics

from Frank Close

OF the four natural forces only electromagnetism and gravity are very well understood. Theoretical developments during the past few years have produced candidate theories of the other two natural forces—the weak force of radioactivity and the strong nuclear force. 1978 saw the dramatic and extremely beautiful experiment at Stanford, California which discovered parity violation in electron-proton scattering (*News & Views* **274**, 11, 1978). This provided significant evidence supporting the model of the weak interaction developed over seventeen years by Glashow, Salam and Ward and by Weinberg and which became a candidate theory following work of 't Hooft in 1971. For the first time we appear to have a theory of the weak force which violates no sacred principles such as relativity, unitarity and causality, is renormalisable (does not have unwelcome infinite probabilities in it), is being increasingly confirmed by data—and could even be correct.

In addition to having apparently uncovered another of Nature's secrets we have obtained a bonus, namely that the weak and electromagnetic interactions are not two independent phenomena but are intimately unified (an intellectual achievement comparable with Maxwell's unification of electricity and magnetism). The above success has been brewing for the past 5 years and has been well described in the scientific press (*Nature* **264**, 505; 1976; **273**, 99; **274**, 11; **275**, 267; 1978). Meanwhile, encouraged by this achievement much enthusiasm and effort has been devoted to developing a theory of the strong force—the one remaining force without a satisfactory candidate theory.

An elegant theory of the strong interaction has been recently developed and is known as 'quantum chromodynamics'. It has all the desirable necessary theoretical properties outlined above for the weak theory, and indirect clues gathered over the past few years have provided qualitative support for it. What has been lacking is a quantitative test whereby the theory can be eliminated if it fails. Two experimental collaborations at CERN, Geneva, have performed such a test and the results appear to be in agreement with the theory. Hence 1978 may go down in history as the year in which two of Nature's forces were at last revealed.

A theory of quark interactions

Quantum chromodynamics (QCD), the theory of the strong interaction, is almost identical to quantum electrodynamics (QED), the theory of the electromagnetic interaction. There is one minor difference between them which turn out to have far reaching consequences.

In QED the fundamental particles (leptons and quarks) carry electrical charge and couple to photons, the quanta of the electromagnetic field. The strength of the coupling is proportional to the charge of the particle There is only one type of charge; like real numbers it can be positive or negative Mathematically this is a U(1) field theory. Particles which do not contain electrical charge do not couple to the photon Hence electrically neutral neutrinos do not couple to photons, nor do photons couple to other photons directly as they are also electrically neutral

It has been known for several years that quarks carry another type of charge called colour. Leptons (such as the electron) do not possess this charge. One immediately suspects that the strong force is somehow connected with this colour charge seeing that quarks do feel the strong force and also carry colour charge whereas the colour neutral leptons do not experience the strong interaction One therefore creates a quantised field theory of chromodynamics—the interaction of coloured charge with 'gluons', the quanta of the chromodynamic field—and hopes that this will have relevance to the strong interaction This is in complete analogy to electromagnetism The gluons are the analogues of the photon and are massless, vector (spin$^+$) particles.

The one essential difference between QED and QCD is that whereas there is but one type of electrical charge in QED, the colour charge has three independent varieties (often called red, yellow and blue charges by analogy with the primary colours) Mathematically this threefold charge yields an SU(3) field theory as against U(1) for QED This has the consequence that gluons themselves carry colour charge whereas in QED photons do not carry (electrical) charge; for example a red quark annihilating with a yellow antiquark will yield an orange (red-yellow) gluon There is a total of eight coloured gluons as against just one photon in QED

Coloured gluons couple to any particle which carries colour charge. The gluons themselves have colour. Hence gluons can couple directly to other gluons. This essential difference from QED, where photons being electrically neutral do not self couple, yields profound consequences but for which our Universe would have been very different, or even nonexistent

Asymptotic freedom

QCD makes specific predictions as to the strength of the quark to gluon coupling. Its absolute magnitude is not understood (just as no-one has yet understood why the electromagnetic coupling has the magnitude $\alpha=1/137$). However, the coupling is predicted to have an effective dependence upon the interquark distance. This dependence has been confirmed in recent experiments. To illustrate what we mean, first recall the more familiar case of electromagnetism

When a charge is placed in a dielectric it polarises the surrounding material. The effective strength of this charge, as measured by the force on

---

F. E. Close is with the Theory Division, SRC Rutherford Laboratory.

0028-0836/79/0277—0349$01.00

a second test charge, will depend upon the separation of the two charges because when the separation is less than the intermolecular spacing the full effect of the charges will be felt without any dilution from the polarisation of the surrounding dielectric whereas at larger separations the polarisation dilutes the charge density. If we insist that the force is Coulombic, then we will be forced into concluding that the effective charge has increased at short distances.

The same phenomenon obtains in a vacuum where an electron surrounds itself with a cloud of virtual electron-positron pairs. A detailed study of QED confirms this heuristic picture: the value of α is not a constant but increases at short distances.

In QCD the prediction is precisely the opposite: the effective coupling decreases at short distances. This is essentially because the gluons now carry charge themselves (in contrast to the photons of QED) and tend to transport the charge of the source away from the source and into the surrounding cloud of virtual quark-antiquarks and gluons.

Hence if a very high frequency short wavelength beam probes the space-time structure of the proton at short distances, it will see a collection of effectively free quarks. This phenomenon was discovered ten years ago and was somewhat paradoxical since if quarks were indeed free then why did they not float freely out from the proton?

QCD appears to provide the answer to this paradox. It predicts that the quarks are free at asymptotically short distances, as observed As the quarks are pulled apart so the force increases. Hence at large distances the interquark force is large and they are confined in the proton. This property of the quarks has suggested the comparison of the proton to an ideal prison—perfect freedom inside but no-one can escape.

Testing QCD

The above is a pleasing resolution of a paradox—free confined quarks—but is hardly sufficient to confirm a theory. What are needed are quantitative predictions to test. Last summer a collaboration from Aachen, Bonn, CERN, London, Oxford and Saclay produced data on very high energy neutrino-nucleon interactions at the CERN-SPS which appear to provide the first dramatic quantitative test of the theory (Bosetti *et al. Nucl. Phys.* **B142**, 1; 1978). A recent paper from a CERN-Dortmund-Heidelberg-Saclay collaboration (de Groot *et al.* CERN report) has provided independent confirmation of these results.

What has been shown is that there are gluons as well as quarks in the proton. The gluons have been shown indeed to be vector particles (like the photon and as required by QCD). The short distance interquark force cannot be probed to infinitesimal distances because the experiment is limited to finite energy. By tuning the energy one can measure the distance dependence of the quark-gluon coupling. The quantitative behaviour was found to be as predicted by the theory.

These are all solid clear cut tests of the theory. There are also some hints in the data that may provide support for the prediction that the gluons can couple to each other (as a result of their carrying colour charge) but this will require much more study before being fully proved.

Another test of the theory involves electron-positron annihilation. At high energies the particles produced appear to come in two jets, as expected if they are the products of a fast quark and antiquark that have been produced in the e^-e^+ annihilation. If the e^-e^+ produce a massive vector meson like the ψ/J at 3.1 GeV or the Υ at 9.4 GeV, then QCD predicts three jets. This is because the meson turns into three gluons; three being the minimum number allowed by the various conservation laws. The ψ/J is too light to allow a good test of this prediction Studies of the more massive Υ at DORIS, Hamburg, are beginning to provide data supporting the three jet prediction. These tests will be high on the list of priorities of the early physics at PETRA, the new high energy electron-positron machine at Hamburg.

In 1979 we can hope to see QCD established as the theory of the quark force. If, as seems probable, it is confirmed then we will have theories of weak, electromagnetic and strong forces. The former pair are already known to be intimately linked and unified. Their similarity in structure to QCD, if verified, hints at more than coincidence and promises that all three may be related or unified.

Ideas on this are already being developed in anticipation. Experimental confirmation of QCD will be a milestone as another of Nature's forces will have been revealed. It seems possible that the dream of synthesising all of the natural forces may soon be realised with potentially profound consequences

There is great optimism that the experimental discoveries of 1979 will be pointing us down this road. This would be an apt celebration of Einstein's centenary as it was his genius that gave us the theory of the remaining force, gravity. Furthermore he spent a substantial part of his later life attempting to build a unified theory of the natural forces. If we are indeed on the verge of verifying QCD, and if unification with the electro-weak interaction is next, then the final step will be to include gravitational interaction ☐

Immunology of malaria

from F. E. G. Cox

THE possibility of producing a vaccine against malaria, probably the most important disease in the world, is one of the major challenges facing biomedical scientists today. This is a field for optimists for, as the pessimists point out, there is no immediate possibility of such a vaccine On the other hand, over the past few years progress in our understanding of the immunology of malaria has been phenomenal and it is important at this point to take stock and to assess the possibilities of vaccination and also, assuming that an effective vaccine can be produced, the problems inherent in making it acceptable. The World Health Organisation has encouraged most of this recent work and the purpose of a recent workshop* was to review our present state of knowledge of this subject.

In malaria, sporozoites injected by a mosquito circulate in the blood for about 30 min before entering the liver to undergo the first stage of multiplication. Invasive stages, the merozoites, flood from the liver and invade red blood cells in which further multiplication occurs, resulting in more merozoites, and eventually sexual stages, gametocytes, form and these are taken up by the mosquito in which the life cycle is completed. Immunological responses to all stages of the life cycle have been demonstrated but a major problem is that these responses are stage-specific. At present, there are three main candidates for the preparation of conventional vaccines; sporozoites, merozoites and gametocytes. The sporozoite is an obvious target and the possibility of an anti-sporozoite vaccine, pioneered by R. S. Nussenzweig (New York), has been adopted by the US Navy. Successes have been reported using sporozoites inactivated

---

*A Workshop on the Immunology of Malaria was held at the National Naval Medical Center, Bethesda, Maryland on 2–5 October, 1978. It was sponsored by the Naval Medical Research Institute, USAID and the World Health Organisation.

0028-0836/79/0277-0350$01.00

in various ways in several host-parasite models. The main advantage of the sporozoite vaccine is that it does not need an adjuvant while the disadvantage is that it requires a number of immunising injections.

Merozoite vaccines (developed by S Cohen, London) are also effective and the material necessary for preparing the vaccine is now easily and safely obtained but adjuvants are required. Gametocyte vaccines (R W Gwadz, National Institutes of Health, Bethesda) prevent fertilisation within the mosquito but depend on the vertebrate host experiencing an infection This kind of vaccine is effective and academically interesting but hardly acceptable in its present form In addition to these conventional specific vaccines there is also evidence that nonspecific factors play a part in immunity against malaria and may involve the natural killer (NK) cells now being implicated in tumour immunology (A C. Allison, Clinical Research Centre, Harrow; H Wigzell, University of Uppsala)

It is obvious that the vaccines in use at present need to be improved and considerable effort has gone into exploiting the possession of stage-specific antigenic differences and it is in this area that biochemists are coming into their own. The antigens of *Plasmodium knowlesi* from rhesus monkeys have been well studied and merozoite antigens have been analysed by J A. Deans (London), sporozoite antigens by E Nardin (New York) and blood stage antigens by R Schmidt-Ullrich (Boston) However, this work has proceeded little further than the preparative stage at present and work with *P. falciparum* is no farther advanced (R J M. Wilson, London)

The final part of the meeting was devoted to the practicability of developing a vaccine suitable for use in humans The need for carefully controlled trials and the difficulties inherent in these were stressed by I A McGregor (Gambia) and the possibility of having to accept some risks and only partial success was raised by R D Powell (University of Chicago, Chicago). Because of the need for safety and the difficulties in finding volunteers and naive populations in endemic areas, the successful development and perfection of a vaccine may present even greater problems than discovering one.

It may be that asking a group of malaria immunologists if they believe in a vaccine is like asking the College of Cardinals if they believe in God but the general consensus of opinion from the meeting was that scientists should be asking when a malaria vaccine could be developed, not if, and this opinion must justify the World Health Organization's faith in such a possibility □

The surface photoelectric effect

from John Pendry

One of the theoretician's favourite models of a solid is a box in which the potential is constant so that the electrons move around freely The mathematical simplicity gained by neglecting atomic scattering enables a comprehensive treatment of the problem to be made; in particular the surface of the box can be studied in detail. There is a competition between the electrons' desire to stay inside the attractive potential of the box, and the tendency to spill over the surface and so reduce the kinetic energy The situation is made doubly complicated because of the charge on the electron which means that as the electron wavefunctions are modified, the potential changes as well. A self-consistent determination of the electronic wavefunctions and the surface potential must be made to discover the height of the potential barrier at the surface, and its shape, particularly its width, which reflects the degree to which the electrons spill over the surface This surface potential is important for certain applications such as the study of chemisorption at a surface, or electrical properties of surfaces An alternative way of viewing the electrons' response to the surface is to treat them collectively as a dielectric medium which screens the bare surface potential of the original box without the electrons This collective view is particularly appropriate when a time-dependent perturbation, such as a photon, disturbs the system The electrons are caused to oscillate collectively and are known to exhibit characteristic resonances at the surface-plasma frequency. This frequency is determined by the details of the surface, as is the distribution of the charge that takes part in the collective oscillation Again these surface plasma oscillations dictate some of the basic properties of the surface

Surprisingly enough, it is believed that this idealised model of free electrons is quite close to the truth in simple metals such as sodium, potassium, magnesium or aluminium. It fails of course when the atomic character of the electron orbitals persists in the solid, as in the transition metals. The existence of a large body of theory for this tractable model, and the physical realisation of the model in several easily available materials could be expected to lead to a rapid growth in our understanding of the surface potential and the surface plasma oscillations This has not been so. Interpretation of the major experimental technique, photoemission, has many complications and it has not been easy to vary enough parameters to get a comprehensive picture Recently Petersen and coworkers (*Zeitschrift fur Physik* **B31**, 171; 1978 and *Phys Rev Lett* **41**, 1314; 1978) have used a synchrotron to provide a source of polarised photons whose energy can be varied at will in the 0-25 eV range It seems that experiments with this source can confirm many of the theoretical predictions made in recent years

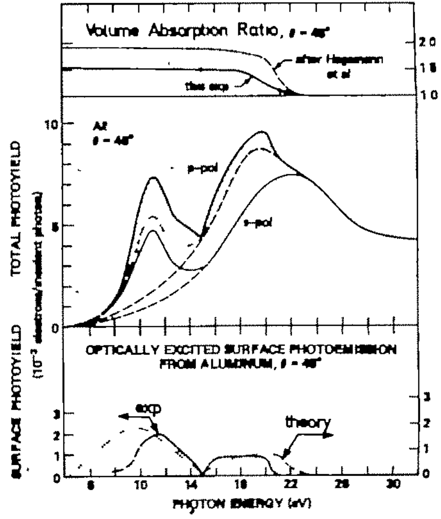

Fig. 1 The results of Petersen for s and p polarised photoemission from an aluminium surface.

In an extremely simplified picture of photoemission, the emitted current I of electrons is proportional to

$$I \propto \sum_{i} |\langle\psi_i| \mathbf{A}\cdot\nabla V |\psi_f\rangle|^2$$

where ψ_i is the electron wavefunction before excitation, ψ_f the wavefunction after excitation, **A** is the A-vector of the electromagnetic field, and V is the step in potential at the wall of the box, which confines the conduction electrons inside the box It is commonly called the surface barrier, and in the free electron model at least is a function only of the coordinate normal to the surface We can easily understand the occurrence of both **A** and ∇V in the expression for the current: the photon described by **A** provides the energy to excite the electron, but

---

J. B Pendry is at the Daresbury Laboratory of the Science Research Council.

carries hardly any momentum, ∇V on the other hand is a source of momentum normal to the surface and allows both energy and momentum to be properly conserved in the transition. I should add that in a rigorous treatment other terms appear that are due to inhomogeneity of A(r) at the surface. Obviously our equation provides a means of checking both the variation of charge density at the surface (which determines V) and the dielectric properties (which determine A, given the conditions of incidence).

Complications arise on two accounts: (1) The potential inside the solid is not perfectly constant and ∇V will have volume in addition to surface contributions; (2) the critical parameter in the equation above is the angle between A and the surface normal. Any roughness of the surface will spoil the simple predictions Complication (2) is much more critical than might have been suspected. even small inhomogeneities in the surface can excite the surface plasma oscillations which propagate away from the inhomogeneity and change the **A** vector over a large area Both (1) and (2) have to be subtracted before comparison with theory can be made.

By changing the polarisation of the light from s ($\mathbf{A}_s$ parallel to the surface) to p ($\mathbf{A}_p$ perpendicular to $\mathbf{A}_s$) the true surface effect can be switched on. Figure 1 shows Petersen's results for s and p polarised light. When the s results have been renormalised to correct for the larger reflectivity of s light they give the contribution only for effects (1) and (2) to the p polarised results. The remainder results from the $\mathbf{A}.\nabla V$ terms which is of course zero for s light. The lower panel in Figure 1 shows comparison of the corrected experiments with theory (Endriz *Phys. Rev.* **B7**, 3464; 1973) taking account of surface plasmon effects in addition to the simple term shown in the equation. The results are encouraging but reveal that theory has some way to go before a complete description is available. At least the new generation of experiments are now providing the checks on theory required to stimulate further advances. ☐

Non-ideal plate tectonics

from Ron Oxburgh

THE general character of the large scale tectonic plates that make up the surface of the Earth is by now fairly well known So too are their present day motions as they separate, allowing warm ductile rock from below to well up and congeal onto their trailing edges; as they slide past each other, or as they converge, on sliding beneath another to be assimilated once more into the Earth's mantle Three lines of evidence may be used to constrain these motions: spreading rates, earthquake slip vectors, and the trends of transform faults, all are employed in a recent analysis of plate motions by Minster and Jordan (*J. geophys. Res.* **83**, 5331; 1978).

They estimate spreading rates from the distance of a characteristic magnetic signature on the ocean floor (anomalies 2 and $2'$) from the ridge crest at which it was formed; the rates are thus averaged over a narrow and well constrained time interval of about 3 million years Earthquake slip vectors and transform fault trends allow the direction of relative motion between two plates to be determined; the former are established by studies of the first motions associated with a particular earthquake observed in different parts of the Earth, and constrain or define the relative motion on the plate boundary where the earthquake occurs. However, the best directional constraint is provided by transform faults; they must lie along small circles parallel to the direction of movement between the two plates, as along them plates neither separate nor converge.

Minster and Jordan use 110 estimates of sea-floor spreading velocity, 78 transform fault azimuths and 142 earthquake slip vectors to construct a world-wide, internally consistent model for motions between 11 surface plates They show that this new data set provides a model which is free of most of the inconsistencies of earlier syntheses and with one major exception, fits all observations extremely well. The exception is the boundary of the Indian plate with the Antarctic and Pacific plates where there are systematic misfits Although this could be the result of observational errors the authors point out that it could also be the result of internal shortening within the Indian plate in a northwest–southeast direction at a rate of about $1\ \text{cm yr}^{-1}$.

Clearly one must hesitate before accepting an interpretation which involves an assumption diametrically opposed to that upon which the model was constructed in the first place, that is, that plates are internally rigid One must ask whether in that case the Indian plate is the only one undergoing internal deformation and, if not, whether the fit achieved elsewhere may not be fortuitously good.

The answer to these questions is probably that the authors are right. A somewhat improbable pattern of observational errors would be required; and, on the other hand, the Indian plate is sufficiently unusual in several other respects that it could be different in this way too; not only did it move northwards during the Mesozoic at, by plate tectonic standards, the breakneck speed of $17\ \text{cm yr}^{-1}$, but after the collision of the Indian and Eurasian continents continued to do so at a significant rate (the Minster and Jordan data suggest about $5\ \text{cm yr}^{-1}$). The interaction of the two continental masses must interfere with steady subduction along the northern boundary of the plate and give rise to anomalous stress conditions within it. It is worth pointing out that the plate is also the site of a massive and unexplained geoid anomaly—the geoid (the gravitational equipotential surface) is depressed about 110 m below its expected value.

The interaction of the Indian and Eurasian plates finds its most spectacular expression in the Himalayan Mountain chain Very different in character, but apparently developed almost simultaneously, is the Tibetan plateau immediately to the north. The plateau is a lozenge-shaped flat area of over a million km^2 bounded by mountainous zones of folded and faulted rocks. The plateau was beneath sea level at the end of the Cretaceous period and has subsequently been elevated without significant folding to a height of about 5,000 m. There has been extensive young volcanic activity within it during the uplift and continuing to the present.

Relatively little is known, at any rate in the West, of the geology of this fascinating area It is therefore hardly surprising that two separate groups, Molnar and Tapponnier (*J geophys Res.* **83**, 5361; 1978) and Ni and York (*J. geophys. Res.* **83**, 5377; 1978) have taken the opportunity of studying it by means of the new ERDA LANDSAT photographs and interpreting these along with slip vector information derived from earthquakes occurring within the area. Both arrive at the interesting conclusion that although in the Himalayas along the southern margin of the plateau there is thrust faulting, within the plateau there are north–south trending normal faults with the formation of rifts, and indicating an extension in an east–west direction. There is also strike-slip faulting in a WNW–ESE trend. It seems

E. R. Oxburgh is Professor in the Department of Minerology and Petrology, University of Cambridge.

therefore as if the Tibetan plateau is responding to compression from the south not by folding but by a kind of lateral extrusion. This requires a ductile behaviour in the underlying crust and upper mantle, a condition which is compatible with an observed strong attenuation of elastic waves beneath the region.

Molnar and Tapponier take the further step to suggest that the ductile lower crust and upper mantle beneath the Tibetan plateau may be regarded as the working fluid in a massive geobarometer, the elevation of the plateau reflecting the level of stress transmitted to the fluid contained by surrounding but uncoupled blocks. The authors essentially propose the decoupling of a thin and more or less passive brittle, upper crustal layer from a ductile zone beneath, which experienced relatively homogenous crustal shortening. It does seem, however, that the amount of isostatically compensated crustal shortening required to 'pump up' the Tibetan plateau to 5,000 m is very large (of the order of 100%) and this would involve a much larger strain in the overlying plateau than is observed.

Molnar and Tapponier may not have solved the problem of plateau uplifts—there are other comparable but smaller features such as the Colorado plateau—but they have refocused attention on the long standing problem of how stresses are transmitted through the lithosphere to produce localised strains. The deformation is clearly inhomogeneous and there is much to be learned about the formation and decoupling and interaction of small scale crustal and lithospheric blocks. The combined application of the methods of earthquake fault-plane solutions, surface geology, gravity, and elastic wave attenuation studies offer a promising way forward. ☐

Life at low Reynold's number

from Paul Colinvaux

SMALL planktonic animals must feed in water which has properties a little like those we know in treacle, as the size and slow motions of the zooplankters make them live at low Reynold's number, at which liquid flow becomes laminar. One of the properties of laminar flow is that raking or stirring movements do not jerk particles through the water so that there is no easy displacement of suspended matter. Planktonic herbivores respond to this reality by generating a flow of water towards themselves and then 'filtering' the flow for algal food. Operating a filter seems an indiscriminate mode of feeding and one wonders whether one of the consequences of life at low Reynold's number is that zooplankters are of so catholic a taste that they eat everything caught in their 'filters'. If they do, it seems curious that the algae of the phytoplankton have evolved so many shapes and sizes. Zooplankters must also cope with the consequences of living in a transparent medium. Rapid motion is forbidden by the low Reynold's number and there is nowhere to hide. Their fluid environment also tends to be layered, warm on top and cold underneath. The strategies adopted by zooplankters to deal with these conditions were explored at a conference on the structure of zooplankton communities held at Dartmouth College New Hampshire*.

We now have a better idea of what 'filtering' really means because the process has been watched by high-speed cinematography through a microscope (J. R. Strickler, University of Ottawa; J. J. Gilbert, Dartmouth College). It turns out that food is often 'handled' rather than 'screened'. A long filamentous diatom colony, for instance, is manoeuvred by a copepod to be end-on to the mouth, then fed into the jaws and broken up like brittle spaghetti. Larger fragments vanish down the animal's mouth but smaller fragments drift away. In a feeding rotifer, a stream of water flows against the ciliated wheel, where different algal cells are accepted or rejected as they thump against the cone that leads to the rotifer mouth.

Data on what particles are removed from suspended mixtures also show that herbivores in the plankton do specialise to some extent but that the discrimination is fairly crude, usually by size or against the obviously scarcely edible. Copepods and rotifers discriminate more than do cladocerans.

The habit of swimming up by night and down by day (vertical migration) has various possible advantages. It hides zooplankton from predators that hunt by sight. But the habit can also result in a systematic food search and it also ought to let plankters lower the energy cost of respiration by putting them in the cold bottom water when not actively feeding. The conference was given strong evidence that all three mechanisms were, indeed, driving the habit, with a suggestion that predation was the most prevalent.

Water mites, which are apparently without serious predators, may migrate up and down, apparently in quest of food or optimum temperature. But plankton in tropical Lake Gatun abandoned a former pattern of vertical migration when their fish predators were removed. In Lake Llano in the Phillipines *Chaoborus* is restricted to water deep enough to let it hide from fish at the dark bottom by day. In the 30 m high experimental chamber at Dalhousie University marine copepods went up and down when the water was essentially without food but abandoned their migrations to remain at an introduced layer of algae. In the Arctic Alaskan Toolik Lake, where there is no night in summer, there was no regular vertical migration but the animals adopted a depth which depended on temperature or their age and hunger.

Another way in which the larger zooplankton avoid predators appears to be by 'cyclomorphosis'. Specimens of some large Cladocera have a significant part of their total volume taken up by essentially transparent protuberances, a change of shape of the growing animal that can be expected to minimise the target presented to a fish

Erratum

In the article 'Epithelial cancer, differentiation and vitamin A' (*News and Views* **277**, 261; 1979) the wrong illustration was inadvertently included. The correct diagram is given below.

hunting by sight. There were more confirmatory data to support the validity of this hypothesis, particularly of the kind that correlates cyclomorphic phenomena with the presence of fish. In addition, it has been nicely shown that the visual acuity of planktiverous fish is of the order expected by the hypothesis so that reducing apparent size is a valid strategy for plankters. There is consensus that predation is, indeed, the selective force behind the cyclomorphosis of the larger cladocerans.

Attention has now shifted to the adaptive responses produced by small invertebrate predators. Some of these are at low Reynold's number like their prey, and have comparatively low success rates. Others, like *Chaoborus*, can cross the Reynold's number divide, make fast capture movements, and wait in ambush on vertical migration paths. The rotifer *Asplanchna*, an animal not much larger than the other rotifers on which it preys, is most successful against victims that are not spiny, suggesting that spines are an adaptation to *Asplanchna* predation. *Heterecope* predation can induce the possession of spines in prey populations rather as fish predation induces cyclomorphosis in Cladocera. There was a general feeling at the conference that small predators may be more important in producing structure in zooplankton communities than competition between herbivores.

With filtering, vertical migration, and cyclomorphosis becoming understood we may claim to be mastering some of the immmediate causes of community structure in the plankton. The underlying causes remain obscure. The difficulty in deciding even whether responses involve selection or merely phenotypic plasticity can be gauged by the fact that there still seems uncertainty about what constitutes many planktonic species. Taxonomists hesitate to put names on tropical zooplankters, not feeling sure whether many of these can be fairly assigned to species known from temperate latitudes, and there seems a growing doubt that species from temperate Europe and North America are really the same even though they look extremely similar. A further question is how much of the response to selective pressures such as predation can be genetic when typical populations are asexual clones?

One particular peculiarity was called to mind by several observations from the tropics: there are usually very few species of zooplankter in the open water of a tropical lake, perhaps one or two copepods, one or two cladocerans, and a few rotifers. This comparatively tiny assemblage of herbivores feeds on an array of phytoplankton species that may number 200 or so different kinds. On land, such an array of plants always seems to be under pressure from many different herbivores, and we call on the 'cropping principle' to explain plant diversity. It is an apparent paradox of the zooplankton that natural selection has not provided an array of herbivore species to specialise on the diverse array of plants. Probably the answer to this paradox lies in the fact that the discriminatory powers of planktonic herbivores, so clearly revealed at this conference, are yet rudimentary compared with those of small terrestrial herbivores. ☐

Magnetics, climate and eccentricity

from Peter J. Smith

ONE of the most surprising correlations to have been discovered in recent years is that between fluctuations in palaeoclimate and the palaeomagnetic field—surprising because it is difficult to imagine any possible causal connection between an atmospheric phenomenon and motions in the Earth's fluid outer core. Indeed, so astonishing was the geomagnetism–climate relationship that, when its existence was first hinted at, a good many people were inclined not to believe it. But if there are still any sceptics around, it may be presumed that they never saw the report by Wollin *et al.* (*Geophys. Res. Lett.* **4,** 267; 1977) published some 18 months or so ago. For in it Wollin and his colleagues presented data from several deep sea sediment cores, showing a convincing general (anti) correlation between the intensity of core magnetisation and foraminiferal abundance—which means a correlation between warm climatic stages and periods of low geomagnetic field intensity.

They went even further. Harrison (*Earth-Sci. Rev.* **10,** 1; 1974) and Kent and Opdyke (*Eos* **57,** 237; 1976) had already suggested that any relationship between geomagnetic field and climate may be the result of a third phenomenon; and Hays *et al.* (*Science* **194,** 1121; 1976) had linked ice ages with the obliquity and precession of the Earth's orbit. Wollin and his coworkers therefore plotted not only magnetisation and foraminiferal abundance but also the variation in the Earth's orbital eccentricity as deduced by Van Woerkom (in *Climatic Change* (ed. Shapley, H.) Harvard University Press, 1953). A threefold correlation between warm climate, low field intensity and high orbital eccentricity for the past 0.8 Myr was thus revealed, the clear implication being that eccentricity modulates both climate and geomagnetic field.

In view (presumably) of previous scepticism on the climate–geomagnetism issue, Wollin *et al.* were rather cautious about the reality of the relationship emerging from their data. But if their new results are anything to go by they need not have worried, for they have now demonstrated a similar correlation in a single North Atlantic sediment core spanning no less than the whole of the past 2 million years (*Earth planet. Sci. Lett.* **41,** 395; 1978). This time they used the more recent eccentricity data from Vernekar (*Meteorol. Monograph 12*, American Meteorological Society, 1972), but the result was the same. Warm climate matches low field matches high eccentricity.

But why? For the time being that is anyone's guess; so Wollin and his colleagues have had a go at it themselves. They begin with the premise that because the density of the Earth's core is greater than that of the near-surface zone, the core–mantle boundary is less elliptical than the Earth's surface. They then argue that, as a result, the torque exerted by solar and lunar gravity on the core is smaller than that on the mantle; so the core tends to precess more slowly than the mantle. Moreover, as the Earth's orbit is eccentric, the solar gravitational field acting on the Earth has an annual variation that increases as the eccentricity increases. Therefore when the eccentricity is greater, the difference between the torques acting on mantle and core is greater, and the tendency of the core and mantle to precess at different rates is enhanced.

Wollin *et al.* then go on to suggest that such an increase in the differential procession will lead to perturbations in the core's convective flow of such a type as to reduce the strength of the geomagnetic dipole and hence reduce the effectiveness of the magnetic shield against corpuscular radiation. Anyone else want to try?

Effect of climatic warming on the West Antarctic ice sheet

Robert H. Thomas

Keith E. Rose
Scott Polar Research Institute, Cambridge, UK

Climatic warming could cause increased melting from Antarctic ice shelves. Continued weakening of the ice shelves in this way would result in the ultimate collapse of most of the West Antarctic ice sheet. For complete removal of the ice shelves collapse of the ice sheet and a 5 m rise in world sea level could occur in <100 yr. More realistically, ice-shelf deterioration is likely to be a rather slow process, and even for a major and sustained warming trend ice-sheet collapse would take several hundred years, with most of the associated rise in sea level occurring during the final century. However, little is known about the glaciers that drain the northern part of the ice sheet. These glaciers have little or no protective fringe of ice shelf and, unless they flow over sufficiently high bedrock sills, they may show a more rapid response to increased temperatures.

MERCER warned recently[1] that increasing levels of atmospheric CO$_2$ may lead to climatic warming that is sufficiently magnified in high latitudes to cause the demise of the Antarctic ice shelves and the inevitable collapse of the West Antarctic ice sheet, leading to a 5 m rise in world sea level. Although at present, parts of the Ross Ice Shelf seem to be growing thicker[2], Mercer's warning cannot be dismissed lightly as the West Antarctic ice sheet is undoubtedly buttressed by ice shelves, and these ice shelves are highly susceptible to changes in climate. Mercer suggested[2] that significant climatic warming may be imminent if not already in progress, and here we try to estimate how rapidly ice-sheet collapse could occur and which parts of the ice sheet are most susceptible. First, however, we stress the need for more sophisticated modelling of climatic response to changing levels of atmospheric CO$_2$ since there is no general agreement regarding the sign, let alone the magnitude, of the response. Here we shall simply assume that warming, for whatever reason, is sufficient to increase ablation rates from Antarctic ice shelves.

The West Antarctic ice sheet (Fig. 1) rests on land that, for the most part, is below sea level[3]. Most of the drainage from the ice sheet is into the Ross and Ronne ice shelves, which have a stabilising influence as ice flowing across the grounding line has to push the ice shelf past its sides and around areas where the ice shelf has locally run aground on seabed shoals to form ice rises. The effect of climatic warming would be to weaken the ice shelves and reduce their buttressing effect so that flow rates from the ice sheet would increase. This would provide negative feedback because the advection of thicker ice from upstream would tend to balance the increased melting rates. In this way collapse of the West Antarctic ice sheet would proceed at a slower rate than would be the case for complete removal of the ice shelves. A full analysis of ice-sheet collapse in these conditions is extremely difficult, but we can estimate maximum retreat rates by making some simplifying assumptions.

Warmer temperatures will weaken ice shelves in two ways—by thinning due to melting at the upper and lower surfaces; and by enhancing existing lines of weakness, such as rifts and bottom crevasses, so that calving rates are increased. Disintegration of an ice shelf by such calving is most likely where the ice shelf is in longitudinal tension. This condition holds over most of an ice-shelf surface except upstream from an ice rise, where longitudinal stresses are strongly compressive and calving is unlikely to occur until the ice rise has disappeared. Once this happens the ice shelf is in longitudinal tension all the way from the grounding line to the ice front and, if accelerated calving does occur, the calving front may recede to the grounding line. In order to incorporate the effects of both increased calving and increased melting within a mathematically tractable model we shall assume that most of the Ross Ice Shelf is instantaneously removed by accelerated calving along existing lines of weakness (Fig. 1). Only the portions of ice shelf that are protected by ice rises remain and these persist until the ice shelf floats free from the seabed shoals beneath the ice rises. We shall restrict our analysis to the two most active ice streams (B and E in Fig. 1) that flow into the Ross Ice Shelf. These ice streams flow along bedrock troughs and they are separated from neighbouring ice streams by ridges or domes of slow-moving ice that rests on bedrock ridges[3]. Outflow from both ice streams is currently restricted by two ice rises within the Ross Ice Shelf—Crary Ice Rise and Roosevelt Island (Fig. 1). We assume that the ice streams are parallel sided and that, as the grounding line retreats, a floating ice shelf forms between the marginal ice ridges (Fig. 2). The seaward grounding line of these ridges will also retreat, but rather slowly because the ice is probably frozen[4] to the comparatively shallow bedrock. In our analysis we assume that during ice-sheet collapse the only restrictions to outflow are

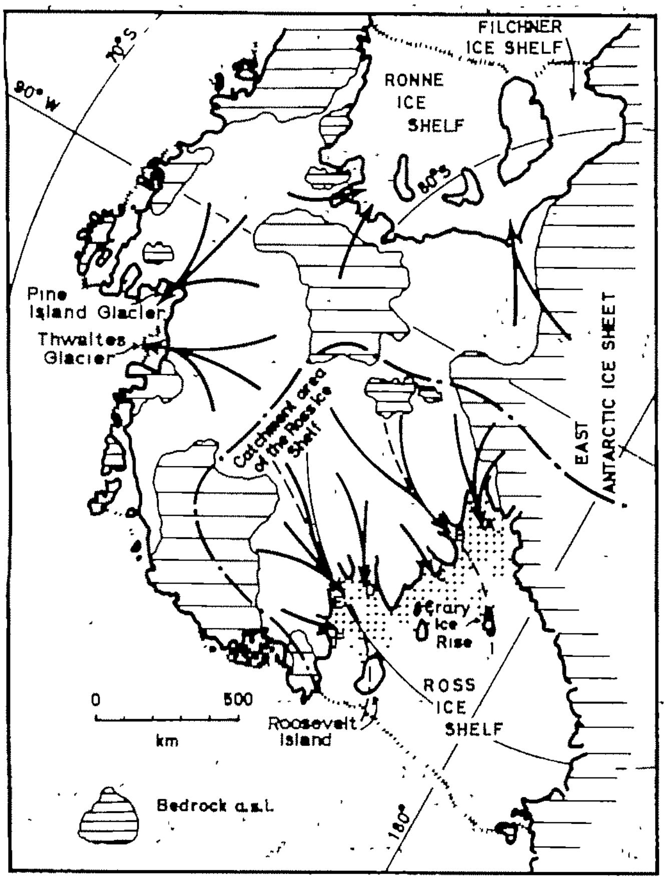

Fig. 1 West Antarctica, showing the areas of bedrock that are above sea level. The arrows represent ice streams that drain the ice sheet. Most of the ice that flows into the Ross Ice Shelf from West Antarctica drains through ice streams B and E. Pine Island Glacier and Thwaites Glacier carry most of the ice that drains northwards. These glaciers seem to be relatively unprotected by bounded or partially grounded ice shelves. Vertical sections taken along the broken lines through ice streams B and E are shown in Fig. 3. In order to calculate maximum ice-sheet retreat rates resulting from climatic warming we assume that most of the Ross Ice Shelf disintegrates very rapidly by calving of icebergs, to leave only the stippled area upstream of the ice rises.

the two ice rises and shear at the sides of the ice shelf that forms within the channel to seaward of the grounding line (Fig. 2). By neglecting the restraining effects of the rest of the Ross Ice Shelf we allow the possibility that accelerated calving may occur, and by assuming instantaneous removal of this portion of the ice shelf we ensure that calculated retreat rates represent reasonable upper limits. We admit that even higher retreat rates can be obtained if we assume instantaneous removal of the entire ice shelf. We have calculated these and we include them in our results, but we stress that they represent limiting values which could never be achieved.

Increased melting will weaken the coupling between the ice rises and the ice shelf, but ice rises will continue to exist and to limit ice-stream flow rates until the ice shelf becomes too thin to run aground. By modelling the form of the ice shelf[5] for given grounding-line positions, marginal constraints, ablation rates and values of the compressive force F between ice shelf and ice rise, we can find the minimum velocity V across the grounding line necessary for the ice shelf to remain grounded on a given shoal. Thus, there is a relationship between F and $V[V=f(F)]$ which holds while the ice rise exists. In addition, equilibrium conditions at the grounding line give an independent relationship[6] between F and $V[V=g(F)]$ in terms of snow accumulation over the ice sheet and of grounding line retreat rate. If the solution of these two equations gives positive values of F and V for a given position of the grounding line then the ice rise continues to exist and the grounding-line retreat rate can be calculated from V. As $F\rightarrow 0$ the influence of the ice rise diminishes until it becomes ungrounded at $F=0$. Thereafter we consider two possibilities: instantaneous calving of the remaining ice shelf so that further retreat is unrestricted, or persistence of ice shelf within the ice-stream channel so that retreat is delayed by shear at the ice-shelf sides. Retreat of the grounding line between ice sheet and ice shelf occurs because the thinning effects of creep and ablation are greater than thickening by snow accumulation and the advection of thicker ice from upstream[6]. In order to calculate the rate of retreat we have used available measurements of snowfall over West Antarctica[7], ice-shelf flow parameters from observations on existing ice shelves[8], and a value for shear stress between the ice shelf and its sides (0.5 bar) which is consistent with observations of floating ice that is flowing rapidly between parallel sides[9]. The effects of advection are incorporated by adopting a relationship between ice-stream velocity V and the product of ice thickness H and surface slope α: $V=C(H\alpha)^m$, where $m=3$, and $C(\sim 550\ \mathrm{m}^{-2}\ \mathrm{yr}^{-1})$ is calculated from the present-day values of $V\sim 550\ \mathrm{m\ yr}^{-1}$ (ref. 10) and $H\alpha\sim 1$ m (ref. 3 and Fig. 3) from near the grounding line of ice stream B. This form of glacier sliding law has some support from theory[11], but it is not expected to be generally valid. Here it is used solely to calculate values of α at high ice velocities, and we have chosen the highest probable values of m and C so that we obtain the lowest probable values of surface slope. This means that we probably underestimate the ice advection term and overestimate grounding-line retreat rates. This approximation is clearly a weakness in our model but it cannot be improved until more is known about the dynamics of fast glaciers and ice streams. Meanwhile our approach is useful as it gives an estimate of the probable minimum time for ice-sheet collapse.

Creep thinning at the grounding line increases rapidly with ice thickness[12], and decreases with increasing back pressure due to ice rises and shear between the ice shelf and its sides[13]. The longitudinal profiles[3] of ice streams B and E are shown in Fig. 3. Once the grounding line retreats down the bottom slope into the deep basin beneath ice stream B creep thinning is controlled by the large values of ice thickness, and retreat is very rapid even for the model that allows increasing back pressure to be exerted by the ice shelf that is assumed to form seaward. Figure 3 shows grounding-line position during retreat plotted against time for different rates of melting beneath the ice shelf. In contrast ice stream E has a comparatively horizontal bed so that creep thinning decreases as the grounding line retreats to leave an ever larger ice shelf within the ice-stream channel. In these condi-

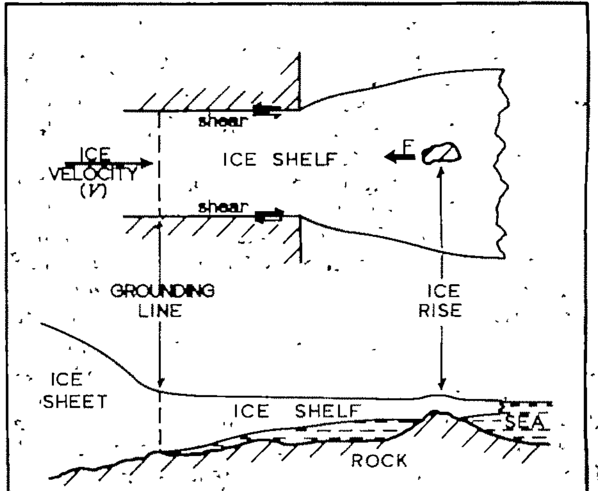

Fig. 2 A retreating ice stream. As the grounding line retreats ice shelf forms between the ridges of slow moving ice that formed the margins of the ice stream. Movement of the ice shelf is restricted by shear past its sides and by the presence of an ice rise where the ice shelf locally has run aground.

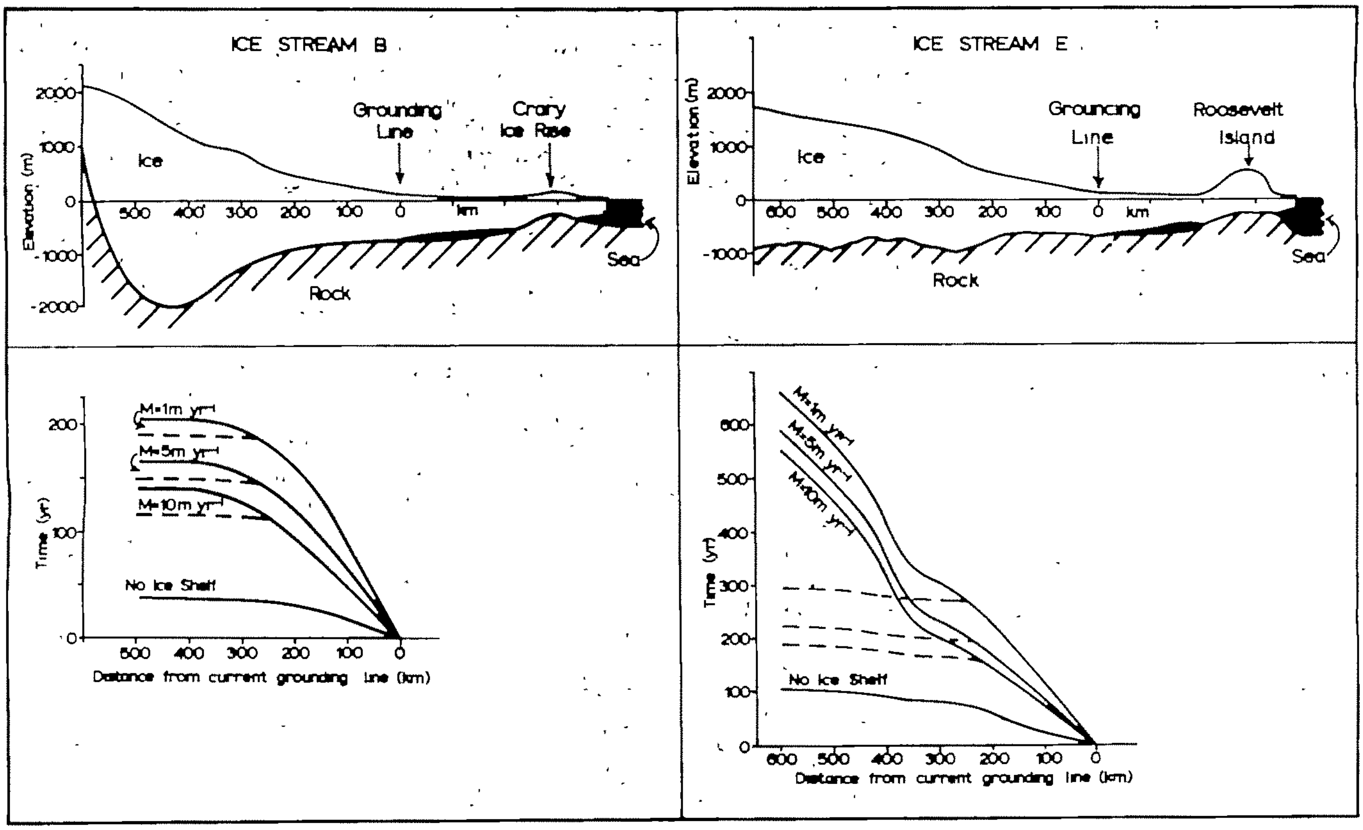

Fig. 3 The longitudinal profiles of ice streams B and E as they are today, and plots of grounding-line position versus time for these ice streams during retreat. Retreat is most rapid if the ice shelf is completely removed, and least rapid for low values of ice-shelf melt rate, *M*. Once the grounding line reaches the deep basin beneath ice stream B retreat is extremely rapid. In contrast, ice stream E flows over a comparatively horizontal bed and retreat rates are ultimately determined by the rate of collapse of the ice-shelf margins. The broken lines show retreat following complete breakup of the ice shelf as the ice rises collapse

tions the grounding line may achieve a quasi-equilibrium position once the ice shelf is so large that creep thinning is sufficiently reduced. However, the ice-shelf margins are themselves retreating and the ice-stream grounding line retreats at approximately the same rate (Fig. 3). Changing the melt rates affects only the time taken for the ice rises to collapse. This is because we have not altered the ablation rate at the grounding line, which we have assumed to be 1 m yr^{-1} in all cases. Unless the climate changes dramatically this is a probable maximum for the ice streams. Melting rates beneath ice shelves may be very high[14,15] and our model allows values up to 10 m yr^{-1} at the ice rise with a linear variation between grounding line and ice rise. Our results underestimate the influence of the ice rises because we have allowed unrestricted lateral creep once the floating ice leaves the ice-stream channels. In reality, neighbouring areas of ice shelf would restrict lateral creep so that vertical thinning would be reduced and the ice rises would survive longer than calculated. Thus, once again, our model overestimates probable retreat rates.

Figure 3 includes plots of grounding-line position against time for retreat with icebergs calving at the grounding line so that there is no ice shelf to restrict outflow. In these conditions collapse of ice streams B and E could occur within 40 and 110 yr respectively, and the rapidly retreating ice stream B would probably capture portions of the catchment areas of neighbouring ice streams to render them more and more unstable. In this way, without the protection of the Ross Ice Shelf, most of the West Antarctic ice sheet could almost completely collapse within 100 yr. However, if we allow ice shelves to persist upstream of the ice rises, retreat is significantly slowed so that total collapse of ice stream B takes between 100 and 200 yr depending on whether ice shelf survives after the ice rises collapse. Equivalent values for ice stream E are 200 and 700 yr but, because of feedback effects, retreat would be accelerated to correspond more closely to that of ice stream B, so that most of the West Antarctic ice sheet could collapse within ~200 yr. However, our assumptions throughout have been biassed to give maximum retreat rates and we stress that we have neglected the buttressing effect of most of the present-day Ross Ice Shelf. Currently, the grounding line of ice stream B seems to be advancing into the ice shelf[2], and in the recent past there may have been widespread grounding and subsequent thickening in the lower reaches of ice stream C (ref. 4). Thus, our estimated collapse rates would apply only after removal of large areas of ice shelf following a major increase in melt rates, probably from the ice/water interface. The shift in oceanographic parameters necessary to effect such an increase would be a rather slow response to climatic change[16], and our calculations take no account of how long this would take. We expect the response time of the oceans to be of the order of hundreds of years[17], so that initial retreat would be far slower than our calculations suggest. Later, as the ocean feels the effect of changing climate and as more of the ice shelf disintegrates, our model would become progressively more applicable. In effect this means that, after the climate starts to change, the first 100–200 km of retreat would take some hundreds of years and then the retreat would follow the pattern shown in Fig. 3. The entire sequence would probably take at least 400 yr, even for a major warming trend of 5 °C per century, and most of the collapse and its associated rise in sea level would occur during the final hundred years. An example of such a retreat sequence was the disappearance of the marine-based portion of the Laurentide Ice Sheet from Hudson Bay. The final collapse took ~200 yr[18], but this was probably the culmination of a retreat sequence that had started considerably earlier.

It is important to consider how relevant these conclusions are to the behaviour of other large ice streams in Antarctica. Available data suggest that the grounding line between West

Antarctica and Ronne Ice Shelf is well protected by large ice rises (Fig. 1) so that probable retreat rates are covered by our analysis. However, the major drainage from the north coast of the West Antarctic ice sheet is through the Thwaites and Pine Island glaciers (Fig. 1), and these terminate in small ice shelves which may or may not be buttressed by ice rises. The stability of these ice streams is dependent on suitably high rock sills near the ice-stream grounding lines. The critical depth (*d*) below sea level of these sills depends to a large extent on ice-shelf dimensions and on the presence or absence of ice rises, but if the fringing ice shelves are unrestricted then *d* may be as low as 400 m for each of these glaciers. Pine Island Glacier may flow into a bounded ice shelf about 50 km square and even this comparatively small ice shelf would exert sufficient back pressure on ice flowing across the grounding line to increase *d* from 400 m to more than 500 m. An increase in ablation rates would be particularly damaging in this area since there is little or no ice-shelf fringe to regulate drainage rates. Little is known about bedrock topography beneath these glaciers but available data suggest that they flow through deep troughs similar to that of ice stream B. If sufficiently high sills do not exist to provide stable grounding-line positions for these glaciers then the northern part of the West Antarctic ice sheet could already be collapsing. Our calculations suggest that, if the seabed at the grounding line of either glacier is 200 m deeper than the equilibrium value, then the grounding line is retreating at 1.5 km yr^{-1} with associated ice velocities of 10 km yr^{-1}. This would be sufficient to raise sea level by approximately 1 mm yr^{-1}. Preliminary estimates of Thwaites Glacier velocities greater than 2 km yr^{-1} have been made by R. Alan of the U.S. Geological Survey from a comparison of satellite imagery with aerial photographs. This is approximately the velocity appropriate to equilibrium with a sill at the critical depth *d*. If this is the case then Thwaites Glacier would be particularly susceptible to any increase in ablation rates.

We conclude that, if the CO_2 greenhouse effect does cause climatic warming that is magnified in polar regions, we do not expect a major increase in ice-shelf ablation rates until ocean warming is sufficient to increase melt rates beneath the ice. Even with a major climatic change and high ablation rates collapse of the West Antarctic ice sheet through ice streams that drain into the Ross and Ronne ice shelves would be restricted initially because the ice shelves would continue to regulate drainage rates, and total retreat would probably take more than 400 yr with most of the associated rise in sea level occurring during the final century. However, much of the ice-sheet drainage is to the north through glaciers that may be unprotected by ice shelves. Unless these glaciers flow over sufficiently high bedrock sills they may be in a very precarious state of equilibrium or they may already be collapsing, and significant warming could rapidly accelerate their collapse. In order to improve our assessment of the stability of these glaciers a detailed survey of their basal topography and velocity measurements on their floating tongues are urgently needed.

Observations from the IDA network of attenuation and splitting during a recent earthquake

R. Buland*, J. Berger & F. Gilbert

Institute of Geophysics and Planetary Physics, Scripps Institution of Oceanography, University of California, San Diego,
La Jolla, California 92093

The project for the International Deployment of Accelerometers (IDA) is intended to provide very low frequency seismic data for the study of Earth structure and source mechanisms. This article outlines preliminary results on attenuation and splitting derived from IDA recordings of a recent large earthquake.

ON 19 August 1977 a very large earthquake occurred about 200 km south west of the island of Sumbawa, Indonesia. The USNEIS hypocentral coordinates are 11.13° S, 118.40° E and 20 km depth. The origin time was 06:08:52.6 GMT. A body-wave magnitude of 7.75 has been assigned by the U.S.G.S. Stewart[1] has estimated the moment to be 10^{29} dyn cm (10^{22} Nm). As this seems to have been the most energetic earthquake since the 1965 Rat Island event it is ideal for the study of very long period free oscillations. The data we have used for this purpose are from the project for the International Deployment of Accelerometers (IDA)[2]. The six stations of the IDA network that produced good records for this event were located at Fairbanks, Alaska (CMO); Ñaña, Peru (NNA); Sutherland, Republic of South Africa (SUR); Halifax, Nova Scotia, Canada (HAL); Brasília, Brazil (BDF); and Rarotonga, Cook Islands (RAR). For the analysis presented here record lengths up to 526 h were used. Part of a typical record (RAR) is shown in Fig. 1. The first 4 h of the recording have been discarded since the large signals saturated the system. Before computing the spectrum, the larger bodily tides have been removed by a least squares fitting procedure and aftershocks have been excised and replaced by linear interpolation.

0028-0836/79/0277—0358$01.00

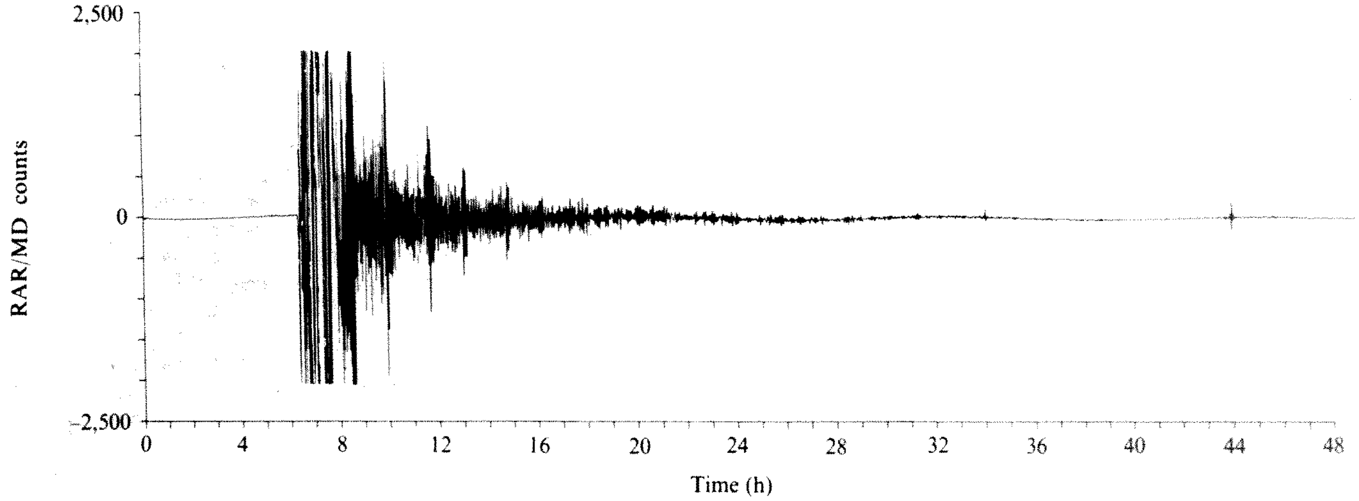

Fig. 1 A 48-h record from IDA station RAR, typical of the data from the Sumbawa event. Note that the instrument was saturated during the first 4 h of the event (through R3). Also Raleigh packets are clearly visible out to R8.

Figure 2 shows the Fourier power spectrum of 155 h of the BDF record beginning 25 h after the event. Clearly present in the spectrum are the fundamental spheroidal multiplets ${}_0S_2$–${}_0S_{21}$, several overtones, and the radial modes ${}_0S_0$ and ${}_1S_0$. The low order multiplets ${}_0S_2$–${}_0S_4$ are obviously split. The quality of the data encouraged us to examine them in more detail and we present here preliminary measurements of frequency splitting, attenuation, and degenerate multiplet frequencies.

Splitting

A multiplet ${}_nS_l$ has $2l+1$ singlet lines. Spherical symmetry causes these lines to have the same degenerate frequency. Deviations from spherical symmetry such as rotation, ellipticity, and lateral variations remove the degeneracy, wholly or partially, and cause the multiplet to be split[3] as may be clearly seen in Fig. 2 for the modes ${}_0S_2$, ${}_0S_3$, and ${}_0S_4$. To investigate this splitting, we can interpolate the discrete Fourier transform (DFT) to a frequency spacing finer than

$$\Delta f = 2\pi/T$$

where T is the length of the time series, by numerically evaluating the trigonometric series approximation to the Fourier integral. A more complete discussion is given elsewhere[4].

Figure 3 shows spectra for ${}_0S_3$ from six individual records. If we count the individual peaks in Fig. 3 we find more than the seven we know must be there. A simple calculation shows that the width (half width at half power) of each singlet is about 9×10^{-6} rad s^{-1} (due both to attenuation and finite record length). Theoretically, the average line spacing for this multiplet should be 1.36×10^{-5} rad s^{-1} (ref. 5). Clearly, the problem is interference between the strong and weak singlets.

There are three ways we know of to resolve the singlets. The first is to increase the record length. Doubling the time series length would narrow the lines to 5.5×10^{-6} rad s^{-1}, but the low amplitude singlets would be overwhelmed by noise. The second method is analytical continuation[4]. This would narrow the lines to 5×10^{-6} rad s^{-1}, but would also decrease the signal-to-noise ratio (S/N) unacceptably. The third method is stacking[6], which enhances the S/N and tends to cancel adjacent singlets. Thus, the only practicable method requires the use of the stations as an array.

At frequencies below 1 mHz we expect that the dominant perturbation from spherical symmetry will be the Coriolis force. Thus, to zeroth order in perturbation theory, the radial (vertical) component of motion of a singlet is proportional to $Y_l^m(\theta, \psi)$, the complex spherical harmonic, in geographical (north polar) coordinates. Each singlet, except $m=0$, is a travelling wave[7]. Let $U(\omega, \theta_j, \psi_j)$ be the spectrum of the vertical component at the j^{th} station. For an isolated multiplet ${}_nS_l$

$$U(\omega, \theta_j, \psi_j) = \sum_{m=-l}^{l} {}_nA_l^m Y_l^m(\theta_j, \psi_j)\, {}_nC_l^m(\omega)$$

where ${}_nA_l^m$ is the excitation coefficient and ${}_nC_l^m$ is the singlet spectrum. Since the spherical harmonics are orthogonal we form the stacked spectrum

$${}_nS_l^m(\omega) = \sum_j \bar{Y}_l^m(\theta_j, \psi_j) U(\omega, \theta_j, \psi_j).$$

where the overscore means complex conjugation. For an isolated multiplet we obtain

$${}_nS_l^m(\omega) = \sum_j \bar{Y}_l^m(\theta_j, \psi_j) \sum_{m'=-l}^{l} {}_nA_l^{m'} Y_l^{m'}(\theta_j, \psi_j)\, {}_nC_l^{m'}(\omega)$$

Dropping the n, l indices we have

$$S_m = \sum_{m'=-l}^{l} A_{m'} \left[\sum_j \bar{Y}^m(\theta_j, \psi_j) Y^{m'}(\theta_j, \psi_j) \right] C_{m'}(\omega)$$

For a large number of uniformly spaced stations the term in brackets approaches a surface integral which equals the Kronecker $\delta_{mm'}$ and $S_m = A_m C_m(\omega)$. Even for a small number of stations one singlet is added always in phase while the others are not and therefore tend to cancel.

Operationally, we must render our six seismograms directly comparable. Therefore, we have removed the instrument phase and normalised the instrument amplitude to a standard response[8]. Finally, we have selected a common time window leaving us with six 155-h records beginning 25 h after the event. Gilbert and Dziewonski[6] show how to avoid discarding data as we have done, but their method involves assumptions about attenuation which we are unwilling to make.

We have applied the spherical harmonic stacking procedure to the multiplet ${}_0S_3$ and representative results are shown in Fig. 4 for $m=-3, 0, 3$. The spherical harmonic stacking procedure has worked well. Using the moment ratio method[4] we have measured all $2l+1$ (that is, seven) singlet frequencies ω_m. This is the first time that a split multiplet has been completely resolved.

Let ω_d be the degenerate eigenfrequency in the absence of rotation and ellipticity of figure. (We ignore other perturbations.) The relation between ω_m and ω_d is

$$\omega_m = \omega_d(1 + a + mb + m^2c)$$

The perturbation parameter b arises from the first order effect of Coriolis force. The perturbation parameter c arises from ellipticity (c_e), the non-radial part of the rotation potential (c_n), and the second order effect of Coriolis force (c_2)

$$c = c_e + c_n + c_2$$

The perturbation parameter a has, in addition,

$$a = a_e + a_n + a_2 + a_r$$

a term a_r from the radial part of the rotation potential. We have

$$a_s + \frac{l(l+1)}{3} c_s = 0 \quad \text{for } s = e \quad \text{and } n$$

Thus $\bar{\omega}$ the mean of the $(2l+1)\omega_m$ is

$$\begin{aligned}\bar{\omega} &= \frac{1}{2l+1} \sum_{m=-l}^{l} \omega_m \\ &= \omega_d\left(1 + a_2 + a_r + \frac{l(l+1)}{3} c_2\right) \\ &= \omega_d(1+p)\end{aligned}$$

From our observations of ω_m we can obtain $\bar{\omega}$, but to obtain ω_d we must have p, a functional of the Earth's structure, given the rate of rotation. Tables of a_s, b, and c_s have been prepared[5]. The value of p changes very little from one acceptable Earth model to another. We are probably justified, at this state of our knowledge, in using the tables to infer ω_d from $\bar{\omega}$. For ${}_0S_3$ we have computed ω_d and $\omega_m^{(\text{com})}$ from $\bar{\omega}$ and tabulated values of a_s, b, and c_s. The comparison is shown in Table 1.

The differences between $\omega_m^{(\text{com})}$ and $\omega_m^{(\text{obs})}$ have been used to compute a (relative) standard error of the mean (s.e.m.) of $\bar{\omega}$ of 1.7×10^{-4}. The perturbation parameter p seems to vary by less than 20% among the acceptable Earth models leading to a relative change in ω_d of less than 8.6×10^{-6}. Thus the relative error in $\bar{\omega}$ can safely be assigned to ω_d as well.

We have also applied the spherical harmonic stacking procedure to the ${}_0S_2$ multiplet. Cancellation is not as good as for ${}_0S_3$ but the frequency spacing between singlets is greater. Again we have completely resolved the multiplet, revealing two of the five singlets which were not visible in the original data. We have computed $\bar{\omega}$, ω_d, and $\omega_m^{(\text{com})}$ (as for ${}_0S_3$) and displayed them along with $\omega_m^{(\text{obs})}$ in Table 2. The relative error in $\bar{\omega}$ is 5.0×10^{-5}. A 20% change in p leads to a relative change in ω_d of 2.1×10^{-5}. Thus, it is reasonable to assign a relative error of 5.0×10^{-5} to ω_d.

The agreement between observed and computed singlet frequencies in Tables 1 and 2 is good evidence that the theoretical splitting formula[5] is correct and that model values of a, b and c are correctly computed and are close to the truth. From the data in Tables 1 and 2 we can determine a best fitting quadratic in m

$$\omega_m = \omega_0 + mf + m^2 g$$

by the method of least squares, where

$$\omega_0 = \omega_d(1+a); \quad f = \omega_d b; \quad g = \omega_d c$$

The results for ${}_0S_3$ are

$\omega_0 = 2.94523 \times 10^{-3} \quad \text{s}^{-1}$

$f = 1.378 \times 10^{-5} \quad \text{s}^{-1} \pm 0.78\%$

$g = -4.27 \times 10^{-7} \quad \text{s}^{-1} \pm 13\%$

where the errors are computed assuming that each $\omega_m^{(\text{obs})}$ is equally accurate. For comparison, model values are

$$f^{(\text{com})} = 1.360 \times 10^{-5} \quad \text{s}^{-1}$$
$$g^{(\text{com})} = -3.47 \times 10^{-7} \quad \text{s}^{-1}$$

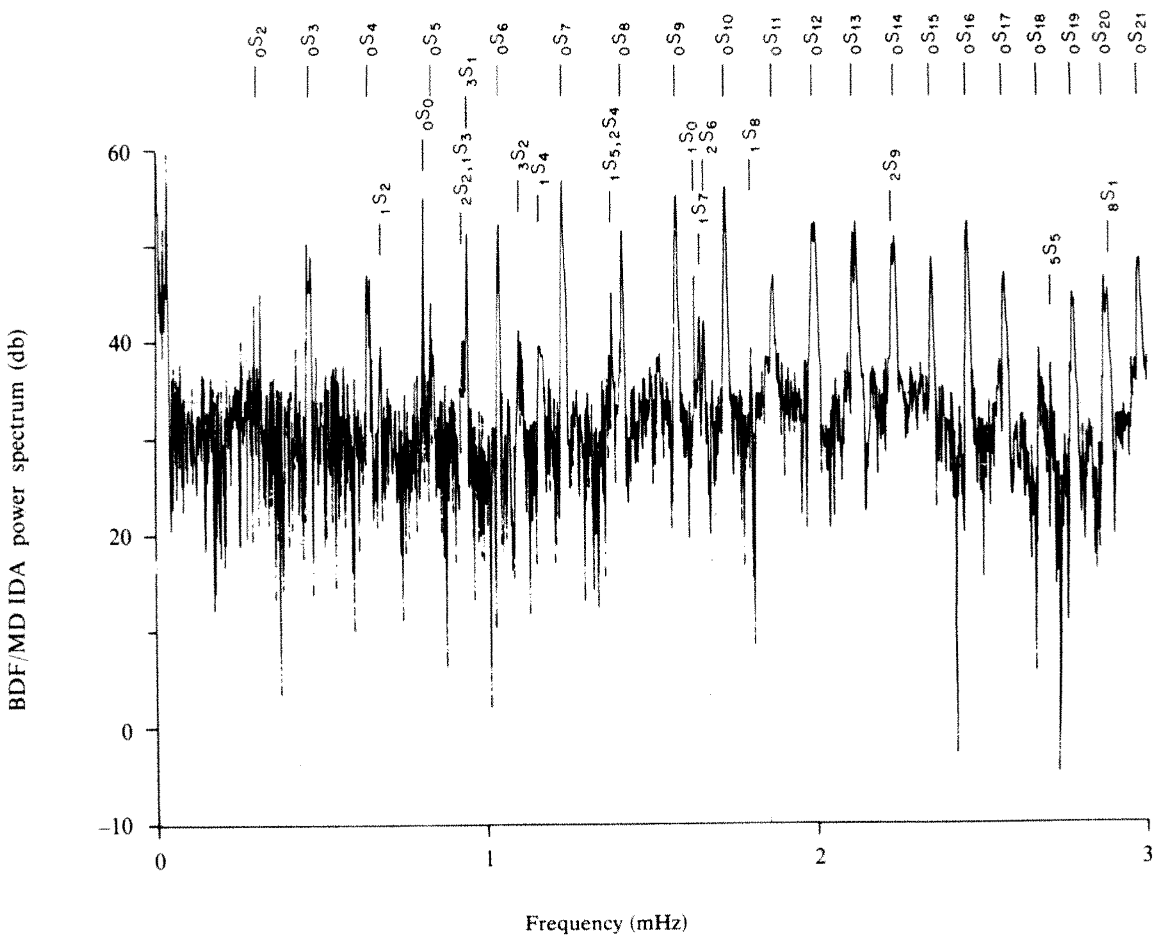

Fig. 2 A log power spectrum of 155 h of record from station BDF beginning 25 h after the event. Note particularly the good excitation of ${}_0S_0$, and many overtones as well as the complexity (due to splitting) of the lowest order fundamental modes: ${}_0S_2$, ${}_0S_3$, and ${}_0S_4$.

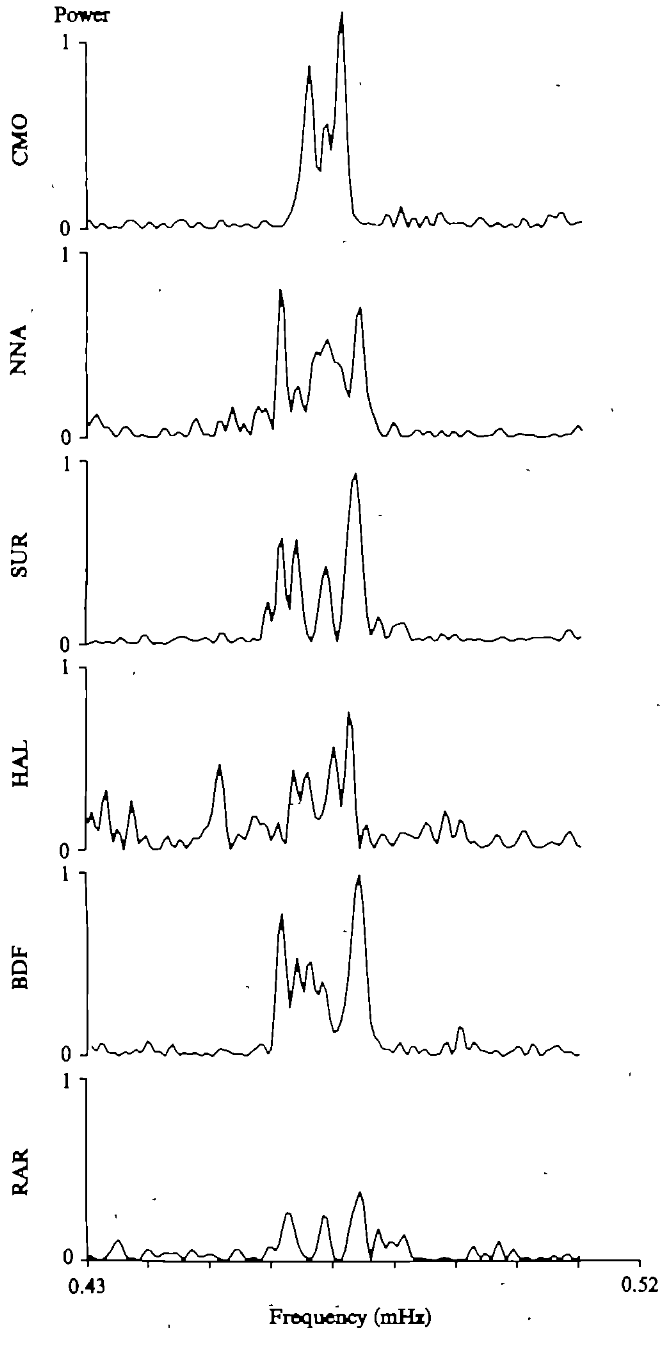

Fig. 3 Interpolated linear power spectra (arbitrary units) of the fundamental mode $_0S_3$ for each of the six stations used. In each case, 155 h of record beginning 25 h after the event were used.

The difference between computed and observed values of f is 1.7σ or 1.3%. For g the difference is 1.8σ or 23%.

The results for $_0S_2$ are

$$\omega_0 = 1.94445\times10^{-3} \quad \mathrm{s}^{-1}$$

$$f = 2.9015\times10^{-5} \quad \mathrm{s}^{-1} \pm 0.46\%$$

$$g = -3.407\times10^{-7} \quad \mathrm{s}^{-1} \pm 31\%$$

The computed[5] values of f and g are

$$f^{(\mathrm{com})} = 2.8973\times10^{-5} \quad \mathrm{s}^{-1}$$

$$g^{(\mathrm{com})} = -5.192\times10^{-7} \quad \mathrm{s}^{-1}$$

The difference between computed and observed values is 0.3σ or 0.14% for f and 1.7σ or 52% for g.

The computed and observed values of f and g are not significantly different at the 2σ level. However, at the 1σ level, only f for $_0S_2$ shows no significant difference. If further research supports the existence of significant differences between observed and computed values of splitting parameters, then the observed values represent new constraints on models of the structure of the Earth. For example, the Fréchet derivative of f with respect to structure is a functional only of the density distribution. Presumably, if one could observe numerous Coriolis splitting parameters, f, one could obtain improved constraints on the density distribution within the Earth.

Table 1 The singlets of $_0S_3$

m	$\omega_m^{(\mathrm{obs})}\times10^3$ s^{-1}	$\omega_m^{(\mathrm{com})}\times10^3$ s^{-1}

	$\bar{\omega} = 2.94352\times10^{-3}$ s^{-1}	$p = 4.3\times10^{-5}$
	$\omega_d = 2.94339\times10^{-3}$ s^{-1}	s.e.m. $= 5.0\times10^{-7}$ s^{-1}

Attenuation

There are surprisingly few really precise data concerning the anelasticity (or Q) of the Earth. While we plan to measure the Q values of all visible modes in our Indonesian data set, for this preliminary report we have decided to concentrate on two unusually interesting modes: $_0S_0$ and $_1S_0$.

The radial $_nS_0$ modes store strain energy primarily in compression, rather than shear[9], and have large Q values. The modes $_0S_0$ and $_1S_0$ in particular have less shear energy than the other radial modes and the measurement of their extremely high Q values has proved to be elusive. Our data set affords us the unique opportunity not only to measure these Q values, but to explore the reproducibility of the results. Our procedure, therefore, will be to examine the six records separately for consistency, and derive our final Q value from the spherical harmonic stack. We measure α_0 where $\alpha_0 = \omega_0/2Q$.

Because of the high Q values of these modes the width of the peak due to record length is large compared with the width due to attenuation for the record length we have. In order to use a Q estimator based on measuring width it is necessary to make the width due to attenuation comparable with the width due to record length (they are equal at 0.885 Q cycles). Conservatively we usually use 1.5Q cycles or over 2,000 h in the case of $_0S_0$. Even at that we would have lost only 3 db over the maximum attainable S/N (at about 560 h according to Buland and Gilbert[4]). This means that such a measurement would be possible, but we would need to edit another 1,500 h of data on each station. For the data set at hand our experiments have shown that a simple time lapse method works as well as anything. We measure the integrated power between half power points in windows lagged so as to have no overlap.

This is a delicate task. To enhance our statistics we need as many windows as possible. But if each window is too short the signal will be overcome by noise. Further, the total time series length T must be long enough so that the mode has decayed somewhat to gain significance. But, if T is too large the latter windows again will have an unacceptable S/N.

Table 2 The singlets of $_0S_2$

m	$\omega_m^{(\mathrm{obs})}\times10^3$ s^{-1}	$\omega_m^{(\mathrm{com})}\times10^3$ s^{-1}
−2	1.88502	1.88489
−1	1.91511	1.91518
0	1.94458	1.94471
1	1.97292	1.97317
2	2.00119	2.00082
	$\bar{\omega} = 1.94376\times10^{-3}$ s^{-1}	$p = -1.04\times10^{-4}$
	$\omega_d = 1.94396\times10^{-3}$ s^{-1}	s.e.m. $= 9.8\times10^{-8}$ s^{-1}

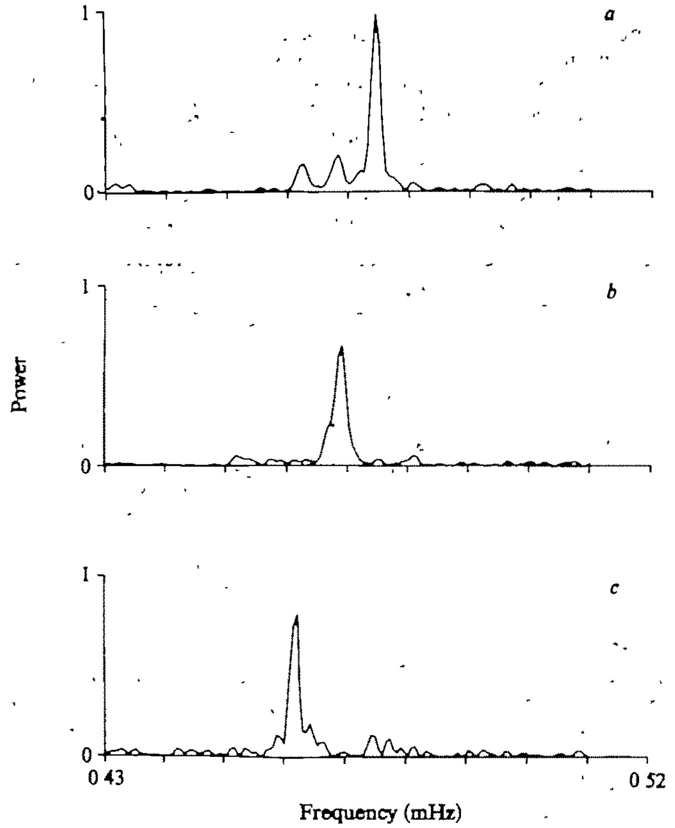

Fig. 4 Interpolated linear power spectra (arbitrary units) of stacks for *a*, ${}_0S_3^{+3}$; *b*, ${}_0S_3^0$; *c*, ${}_0S_3^{-3}$. All seven ${}_0S_3^m$ singlets were resolved.

As a result of these trade offs, we have chosen for ${}_1S_0$ 10^5-s windows in a 150-h series and for ${}_0S_0$ 2×10^5-s windows in as long a series as we can get. Therefore, for ${}_1S_0$ we may work with the six 155-h records described above. But for ${}_0S_0$ we will have to do something more elaborate for a stack, as not all the available records are of sufficient length and some of the records have large data gaps. Because of these gaps a straightforward deconvolution of the series to remove the instrument response would distort good data points adjacent to the gaps. The procedure adopted to avoid this was to correct for instrument response at only one frequency by multiplication of the time series by a complex number that is the reciprocal of the instrument response at the desired frequency. Then time series were averaged point by point with data gaps not included in the average, to form a 575-h stack with few data gaps.

For ${}_1S_0$ we used five windows. The Q results for individual records scatter approximately 50% about their mean with relative errors of the least squares fit ranging between 13 and 63%. Our final value is $Q=2{,}360\pm15\%$, obtained from a 150-h stack. Our final error estimate is the maximum likelihood value derived from the single station measurements. On the basis of the individual record Q values, the final error bound seems to be rather small (it is based on only six data), but not totally unreasonable.

For ${}_0S_0$, the five individual records are of various lengths yielding up to fifteen 10^5-s windows (avoiding gaps). Individual record Q values scatter as much as 80% about their mean with relative errors of the least squares fit ranging between 13 and 105%. For the final (stack) result we used six 2×10^5-s windows (to boost S/N). The result is: $Q=4{,}100\pm26\%$.

Dahlen[10] has extended the work of Munk and Hasselmann[11] on the expected quality of spectral parameters measured in the presence of noise. He considered the linear, least-squares estimation of the (complex) frequency of a decaying sinusoid and obtained expressions for the variance

$$\langle\delta\omega_0^2\rangle=\langle\delta\alpha_0^2\rangle=\frac{R(2\alpha_0T)}{T^2(S/N)}$$

The function $R(x)$ is well approximated by $R(x)=2(x^2+9)^{1/2}$. S/N is the ratio of peak signal to average noise in the power spectrum and T is record length.

Let $\sigma_D^2=\langle\delta\omega_0^2\rangle=\langle\delta\alpha_0^2\rangle$. Our result for ${}_1S_0$ gives

$$\sigma_D=5.0\times10^{-7}\ \mathrm{s}^{-1};\qquad \sigma_D/\alpha_0=23\%$$

for $S/N=20$ db in the radial stack. The assigned relative error of 15% seems reasonable. In the case of ${}_0S_0$ we have

$$\sigma_D=5.4\times10^{-8};\quad \sigma_D/\alpha_0=9\%$$

for $S/N=28$ db in the radial stack. Again, the assigned relative error of 26% seems reasonable.

Frequencies

The observations of all singlets in the multiplets ${}_0S_2$ and ${}_0S_3$ allowed us to infer the gross Earth data, ω_d, for these modes with greatly improved precision:

$$\omega({}_0S_2)_d=1.94396\times10^{-3}\pm9.8\times10^{-8}\ \mathrm{s}^{-1}$$

$$\omega({}_0S_3)_d=2.94339\times10^{-3}\pm5.0\times10^{-7}\ \mathrm{s}^{-1}$$

From the six individual (155-h) records we have measured frequencies for the radial modes ${}_0S_0$ and ${}_1S_0$ with the following results and standard errors of the mean:

$$\omega({}_0S_0)=5.11850\times10^{-3}\pm1.5\times10^{-7}\ \mathrm{s}^{-1}$$

$$\omega({}_1S_0)=1.02532\times10^{-2}\pm1.0\times10^{-6}\ \mathrm{s}^{-1}$$

As $l=0$ there is only one singlet for each of these modes. However, a computed correction must be made to find ω_d as above. The results are:

$$\omega({}_0S_0)_d=5.11679\times10^{-3}\pm1.5\times10^{-7}\ \mathrm{s}^{-1}$$

$$\omega({}_1S_0)_d=1.02498\times10^{-2}\pm1.0\times10^{-6}\ \mathrm{s}^{-1}$$

The standard errors assigned to the radial modes are in agreement with the criterion of Dahlen. So are those of ${}_0S_2$ and ${}_0S_3$ provided we take into account the number of singlets in each multiplet and accept theoretical values for α_0. It would be more satisfactory to use observed values of α_0 and we intend to obtain them.

Discussion

The IDA network has given us the capability to refine our studies of splitting and attenuation, and to improve significantly the resolvability of spectral parameters in the low frequency seismic band. At the time of the Indonesian earthquake there were nine IDA stations, six of which provided the records used in this article. Now there are 14 stations with an additional three scheduled for installation within a year. With an enlarged network we should be able to resolve multiplets of higher order, and improve the accuracy of our measurements of ω_0 and α_0. Improved measurements will lead to greatly improved models of attenuation and laterally heterogeneous structure of the Earth.

IDA data are available from the World Data Center, Boulder, Colorado. The research was supported by NSF grants NSF-EAR77-00897, NSF-EAR77-13630 and NSF-EAR78-02618. The digital seismographs at each IDA station are force-fedback La Coste and Romberg gravimeters. Funds for their acquisition were donated to the University of California by Cecil and Ida Green of Dallas, Texas.

letters

Evidence of a disrupted pulsar binary system

THIS letter demonstrates that the pulsars PSR1952+29 and PSR1929+10 may have originated in a binary system which was disrupted by a supernova explosion less than a million years ago. If further confirmed by improved observations, this result provides an evolutionary link between the separate phenomena of X-ray binary systems and radio pulsars.

PSR1952+29 has a characteristic age of 3,600 Myr as measured by the usual ratio $\tau = P/2\dot{P}$ (where P is the pulsar period and $\dot{P}$ its time derivative). This is the largest known value. PSR1929+10 has a characteristic age of 3.1 Myr, a more typical value. The characteristic age of a pulsar is generally regarded as an overestimate of its true age, and independent estimates[1] based on kinematic arguments suggest that pulsars have a true average age of 2 Myr.

Recent results[2] have given the distance to PSR1952+29 as 240 pc, and its closeness to Earth has made it possible to detect its proper motion (200 km s^{-1}) in both magnitude and direction. Gullahorn and Rankin[3] report this together with similar measurements of PSR1929+10 and six other pulsars. PSR1929+10, whose galactic coordinates are about 20° from PSR1952+29, is estimated to be at a distance of 110 pc and to have a proper motion of 85 km s^{-1}. Both pulsars lie close to the galactic plane (their galactic coordinates are respectively $l^{II} = 47.4°$, $b^{II} = -3.9°$ and $l^{II} = 65.9°$, $b^{II} = 0.8°$), with PSR1952+29 actually having a small velocity component into the plane. The velocity vectors of both pulsars point away from a region of the sky from which they can both conceivably have come within a pulsar lifetime. This leads one to suspect that they began their lives as pulsars in a common event. To test this hypothesis it is possible in principle to determine the coordinates of the coincidence from the coordinates and transverse velocities of the pulsars, then to check that both pulsars were at this point at the same time. In practice, errors in the distances and coordinate velocities of the pulsars will mean that the coincidence is never exact. Here we adopt the procedure of choosing possible galactic coordinates for the coincidence (the best fit was given by $l_0^{II} = 32°$, $b_0^{II} = 3°$) and computing the velocity which the pulsars would have at their present coordinates if they had started simultaneously from this point. Writing the velocities of PSR1929+10 and PSR1952+29 in galactic coordinates as (v_{l_1}, v_{b_1}) and (v_{l_2}, v_{b_2}) respectively, we obtain the fit

$$v_{l_1} = 80\ \mathrm{km\,s^{-1}}\ (78) \qquad v_{b_1} = -35\ \mathrm{km\,s^{-1}}\ (-30)$$

$$v_{l_2} = 167\ \mathrm{km\,s^{-1}}\ (198) \qquad v_{b_2} = -12\ \mathrm{km\,s^{-1}}\ (-39)$$

The observed[3] values being given in parentheses. The computed values lie within the error bars of the observations. For this calculation it is assumed that the pulsars have moved in straight lines in space, neglecting the gravitational force of the Galaxy (which is a second-order effect for such fast-moving objects). If the two pulsars were coincident at a distance r_0 at a time T ago, then the above fit of their present projected motions on the celestial sphere is given by taking the ratio r_0/T as 300 km s^{-1}. In the absence of measured radial velocities, r_0 and T cannot be determined independently from the transverse motions. If, however, we impose the condition that the radial and transverse velocity components are comparable, then a possible choice of parameters is $T = 600{,}000$ yr, $r_0 = 180$ pc, which yields $v_{r_1} = -106$ km s^{-1}, $v_{r_2} = +152$ km s^{-1}.

Most supernova remnants have estimated ages <0.1 Myr (ref. 4). It is usually assumed that after this time they merge with the surrounding interstellar medium[5]. The remnant of the supernova taking place 0.6 Myr ago would now, if detectable at all, be a large diffuse area over 30 pc across[6]. At a distance of 180 pc this would have a diameter of at least 10°. Radio maps[7] do not reveal any such feature centred on the suggested coincidence. However, it is possible to discern a roughly circular feature with a diameter about 7° centred at $l^{II} = 33°$, $b^{II} = 12.5°$. Although fresh data on proper motions could bring about a readjustment of the point of coincidence, an association with this feature must be regarded as highly tentative.

Nevertheless, on the basis of the calculations here it seems possible to suppose that pulsars PSR1929+10 and PSR1952+29 emerged from a binary system which was disrupted by an explosive event ~0.6 Myr ago. As it has the younger characteristic age, one may reasonably assume that PSR1929+10 is the neutron star which was formed in the explosion. Before this, PSR1952+29 will have existed as a neutron star in orbit around a more massive companion which eventually gave birth to PSR1929+10. If confirmed by further measurements, this result provides evidence for van den Heuvel's account[8] of the final phase of binary evolution and supports the suggestion[9–12] that pulsars originate in close binary systems.

Without going into the details of close binary evolution here, we can imagine that the binary experience had two important effects on the neutron star which became PSR1952+29. First, having itself been formed in a supernova explosion between 1 and 10 Myr previously[8], its magnetic field would have had time to decay from its original strength before it was released as a single pulsar. Making the conventional assumption that a pulsar's magnetic field is proportional to $(P\dot{P})^{1/2}$, we obtain a value of 3×10^{10} G for PSR1952+29, compared with 5.2×10^{11} G for PSR1929+10 and 3.8×10^{12} G for the recently-born Crab pulsar. Second, if PSR1952+29 has passed through a spin-up phase (as an X-ray pulsar), then it will have accreted angular momentum from its companion. Its present low braking rate (presumably the consequence of a low magnetic field) implies that its period (0.43 s) has not changed significantly since the break-up of the binary system, but before this both considerable spin-up and spin-down will probably have occurred[12].

A histogram[13] of the characteristic ages of the 89 pulsars with measured $\dot{P}$ reveals that while 68 of them (including PSR1929+10) belong to a convincing power-law distribution tailing off at 20 Myr, an additional 19 pulsars (including PSR1952+29) do not fit this pattern, having anomalous characteristic ages ranging from 22 to 3,600 Myr. The result here strongly implies that the 'anomalous' pulsars have spent a significant part of their lives as neutron stars in binary systems. The existence of two populations of pulsars arising in this way has been suggested by several authors[10–12]. Here we emphasis that the magnetic field will be the factor which distinguishes between them. Precisely this classification of pulsars was made by Helfand and Tademaru[10].

As the experience of PSR1952+29 is not likely to be unique,

S is the approximate transverse separation of the pairs; d, distance to each pulsar; P, period, and τ the characteristic age (data from ref. 13).

it will be of interest to investigate the origins of the remaining 18 anomalous pulsars to see if they have previously unrecognised companion pulsars with whom they once formed binary systems. Some examples of possible 'pairs' are given below in order of increasing transverse separation. Since a pulsar with velocity 200 km s^{-1} travels 200 pc in 1 Myr it is extremely difficult to recognise pairs without accurate velocity vectors, and this list is little more than informed guesswork. The pairs have been chosen on the basis that both pulsars are at roughly the same distance from Earth and are 'reachable' from one another. Assuming the pulsars in each pair have once formed a binary system we have given them in expected order of formation as neutron stars.

The pair PSR1700−18 and PSR1706−16 seems interesting because of their closeness to one another and, as elsewhere on the list, one would at least like to see the question-mark eradicated. Both PSR0809+74 and PSR0904+77 are to be found in a high latitude 'hole' in the galactic HI distribution[14]. The association of the 'hole' (presumably a supernova remnant) with PSR0809+74 has been regarded as suspect on account of the latter's large apparent age. It could be that PSR0904+77 is the missing younger companion. A further list of possible pairs, chosen on a similar basis, is given in ref. 9.

Finally, one should consider the future of PSR1952+29 and PSR1929+10. The characteristic age of the latter shows that it is slowing down on a timescale roughly comparable with pulsar lifetimes and it will presumably switch off when larger values of P are reached. This argument is not, however, available for PSR1952+29. Its emission may fade through the decay of its already low magnetic field, but the lifetimes of this and the other anomalous pulsars need not bear any relation to the typical lifetimes of their former companions.

I thank Dr Peter Biermann for helpful discussions.

Brightest members of clusters of galaxies

THERE are two opposing interpretations of the small dispersion $\sigma_1 \sim 0.35$ mag in the absolute magnitudes M_1 of the brightest members of rich clusters of galaxies measured by Sandage[1]. In one view, advanced, among others, by Peebles[2,3], it is assumed that there is a universal cluster luminosity function, and that the value of σ_1 and of the variation of M_1 with cluster richness can be explained as the statistical result of drawing the brightest member from a set of clusters obeying this function. There is therefore nothing physically remarkable about the brightest member, and its luminosity is determined by the same mechanism as that which determines the luminosity of the fainter members. The opposing view, which has been advanced by Peach[4], Sandage[1], and Tremaine and Richstone[5], claims that the small dispersion is due to special conditions governing the formation or evolution of the brightest member, and is therefore entirely or in part independent of the luminosity function of the other cluster members. On this view one evokes either special conditions at the epoch of galaxy formation[1], or a mechanism, such as galactic accretion[6], which governs the size and luminosity of the most massive galaxy in such a way as to give a small dispersion in the metric magnitude. The weakness of the statistical model, according to its opponents, is its inability to account for σ_1 without postulating a luminosity function steeper than those directly observed. The opposing view is open to the criticism that it is either *ad hoc* or that the mechanisms of galaxy evolution are too uncertain to lead to reliable conclusions. Here, we discuss the two interpretations in the light of new results and suggest that the case against the statistical model may not be as strong as sometimes suggested.

During a programme of photometry of clusters, we have measured the absolute isophotal magnitudes of the brightest members of the 12 rich clusters listed in Table 1. Details of the methods of observation and reduction are the same as those used in our previous work[7–9]; full lists of magnitudes will be published elsewhere, except for A1413, A1656 and A1930, which are already available. After the cluster name we give the redshift z, the cluster richness R, the radius r_{25}, defined as $(a/\pi)^{1/2}$ where a is the area contained within the standard

Table 1 Isophotal magnitudes for the 3 brightest members of 12 rich clusters of galaxies

Cluster	Redshift	Richness class	Isophotal radius (kpc)	Absolute V magnitudes for the 3 brightest cluster members

isophote for the brightest member, and absolute *V* magnitudes M_1, M_2 and M_3 for the first, second and third brightest cluster member measured to the 25 mag arc s^{-2} isophote ($H_0 = 50$ km s^{-1} Mpc^{-1}; $q_0 = +1$). Table 2 gives the dispersions in M_1, M_2 and M_3 for the sample.

The absolute magnitudes M_1 of Sandage, on which the entire controversy has until now been based, have been derived by fitting photoelectric magnitudes measured through a series of circular apertures to a standard growth curve of magnitude against radius from the galaxy centre[10]. The small scatter of the observed points about the growth curve is claimed as evidence that the light distributions of the galaxies in his sample are similar to radii of ~40 kpc. The light contained within a standard metric radius of 43 kpc at the galaxy is inferred from the curve and gives, after absorption and K-corrections, the final metric magnitude. The second and third brightest, M_2 and M_3, were not measured directly in this way, but their magnitudes were calculated on the assumption that the ratio of their luminosities to that of the brightest is given by the ratio of the apparent sizes of their images to that of the brightest; M_2 and M_3 are thus isophotal magnitudes. The dispersions σ_1, σ_2 and σ_3 for Sandage and Hardy's[11] magnitudes for the 78 clusters in their sample and for the 12 clusters of Table 1 are shown in Table 2. It will be seen that the results for the present sample are not significantly different from those for the larger one. It will also be clear that $\sigma_1 = 0.57 \pm 0.18$ for the isophotal magnitudes is about one standard deviation larger than that for the metric magnitudes $\sigma_1 = 0.38 \pm 0.12$, whereas σ_2 and σ_3 are essentially the same. This difference cannot be attributed to measurement errors; we estimate our errors at about 0.2 mag which would imply a corrected dispersion $\sigma_1 = 0.53$ mag.

The reason for the greater spread in M_1 measured to a fixed isophote rather than to a fixed radius can be understood in the following way. The size of the brightest member to the 25 *V* mag arc s^{-2} isophote r_{25} ranges from 32 kpc in A1377 to 61 kpc for the cD galaxy in A1413, with a mean of 42 kpc, fortuitously close to Sandage's standard metric radius. This radius is correlated with the isophotal magnitude in the sense that brighter galaxies tend to be larger, and fainter galaxies smaller, than the mean. As metric magnitudes are measured to a constant radius close to our mean, bright galaxies will possess brighter isophotal magnitudes than metric, whereas faint galaxies will possess fainter isophotal magnitudes, because of the difference in areas contributing to the integrated luminosity in the two methods of measurement. We find that for our sample

$$M_1 = -(7.3 \pm 1.5) \log r_{25} + \text{constant} \qquad (1)$$

Sandage[10] finds a dispersion in isophotal diameters, *d*, for 27 brightest members, after correction for measuring errors,

$$\sigma(\log d) = 0.075 \pm 0.02 \qquad (2)$$

close to the dispersion of our sample 0.080 ± 0.025. Our empirical relationship (1) when combined with (2) leads to a dispersion in the isophotal magnitudes of Sandage's sample of 0.54 mag which is close to our value. We have found that for reasonable functional forms of the radial luminosity distribution (1) is a likely consequence of correlations between the central surface brightness and the isophotal magnitude and between the scale-length of the distribution and magnitude, in the sense that brighter galaxies possess both higher central surface brightness and flatter luminosity profiles than fainter ones. There is some direct evidence for this in the work of Oemler[12].

Geller and Peebles[3] have calculated in detail the predictions of the statistical model using a luminosity function based on Abell's observations of four rich clusters; this function also agrees well with one we have derived for the clusters of Table 1. Table 2 gives their values for σ_1, σ_2 and σ_3. Note that there is good agreement with our isophotal results but a disagreement with σ_1 for the metric magnitudes. They further predict a linear dependence of M_1 on richness class *R* with a slope of $dM_1/dR = -0.2$ mag per class. Sandage[1] has shown that for his larger sample the actual variation must be much flatter. In our present sample of clusters, which is too small to give a good enough value for the slope to enable a direct comparison with the theory, $dM_1/dR = -0.21 \pm 0.25$ for the metric magnitudes and $dM_1/dR = -0.47 \pm 0.31$ for the isophotal. The latter is more than one standard deviation greater than zero and, if confirmed with a larger sample, would be difficult to explain other than on a statistical model.

Table 2 Dispersions in the absolute *V* magnitudes of the 3 brightest members

Magnitudes		σ_1	σ_2	σ_3
Isophotal magnitudes from this work		0.57 ± 0.18 (12)	0.45 ± 0.14 (12)	0.45 ± 0.14 (12)
Metric M_1 and isophotal M_2 and M_3 from Sandage and Hardy[11]	All clusters	0.34 ± 0.04 (73)	0.51 ± 0.06 (74)	0.55 ± 0.06 (74)
	Clusters of Table 1	0.38 ± 0.12 (12)	0.49 ± 0.17 (10)	0.48 ± 0.17 (10)
Predictions of the statistical model (Geller and Peebles[3])		0.53	0.48	0.47

Errors are standard deviations. The number of galaxies in each sample is given in parentheses.

The discussion of the statistical model has been carried further by Tremaine and Richstone[5], who have derived two tests of the model which are more general than those of Geller and Peebles, in that they are independent both of the assumed form of the luminosity function and of its uniformity from cluster to cluster. Assuming solely an asymptotic behaviour of cluster luminosity functions certainly true of all observed functions, they prove that the two parameters

$$t_1 = \sqrt{\frac{N}{N-1}}\,\frac{\sigma_1}{\langle\Delta\rangle} \quad \text{and} \quad t_2 = \sqrt{\frac{N}{N-1}}\,\frac{\sigma_\Delta}{(0.677)^{1/2}\langle\Delta\rangle}$$

must be $\geqslant 1$ for any large sample of clusters. Here, $\Delta = M_2 - M_1$, σ_Δ is its dispersion, $\langle\Delta\rangle$ its mean, and *N* the number of clusters. Their application of the test using the Sandage and Hardy magnitudes gave values of t_2 near unity, but t_1 was significantly less than unity for every sub-set of the data examined. Their conclusion was that no statistical model was likely to be valid. Using the isophotal magnitudes of Table 1, $t_1 = 1.0$ and $t_2 = 1.2$, a result consistent with the model. The change is mainly due to the increase of σ_1. Although the present sample is small, the result again supports the view that the use of isophotal magnitudes may remove the discrepancy between observation and theory.

If the isophotal magnitude is a physically more significant parameter than metric magnitude, being more closely related to the mass of the galaxy, and if a larger sample of clusters confirms our result that the consistent use of isophotal magnitudes removes much of the conflict between the statistical model and the observations, it does not necessarily imply that there is nothing unique about the properties of the brightest member, only that any integrated photometric differences it may have from other cluster members do not exceed limits set by the model. It is possible that cD galaxies are structurally different from other giant ellipticals. There is also a suggestion that there is a steepening of the luminosity function in the denser parts of clusters with particularly bright brightest members, such as the Coma cluster[9], similar to that predicted for galactic accretion; this is borne out in some of the luminosity functions of other clusters of Table 1. However, accretion on the brightest galaxy cannot have proceeded to the point where the galaxy has lost all those properties which are continuous with the properties of the fainter members.

If one accepts these conclusions, it is particularly difficult to maintain the view[1,4] that the smallness of σ_1 is in some way due to special conditions not applicable to other members at the time of galaxy formation.

Nucleation and growth studies by small angle neutron scattering and results for a glass ceramic

THE nucleation of phase separation in bulk solids remains one of the more elusive phenomena in both experimental and theoretical terms[1]. Experimentally, the difficulties centre on the problem of gaining detailed structural information about the small composition fluctuations from which the precipitate develops. Theoretically, progress has been made in calculating stable microstructures in simple materials such as the rare gases[2] and amorphous metals[3] as well as identifying transient clusters in liquids which are precursors to long range order and thus may act as nucleation embryos[4]. However, it remains a formidable problem to relate such calculations to the microstructure of a multicomponent solid or liquid. The most readily observed physical property of nuclei is their ability to facilitate growth of a new phase in appropriate conditions. Consequently, the study of the growth process immediately following nucleation is the most accessible though indirect method of inquiry into nucleation. It is, however, often difficult to follow the very early stages of growth either because it occurs too rapidly, or because the size or total mass of the precipitate falls outside of the conventional range of structural techniques. We report here the striking effects of nucleation as revealed by a neutron small angle scattering study (SANS) of a glass ceramic ($2MgO$, $2Al_2O_3$, $5SiO_2 + 10\%$ TiO_2 nucleating agent) during the early stages of growth of the precipitate. As a result of the continuous viscosity–temperature relationship, the rate of phase separation in glasses can be put on a favourable time-scale to follow the kinetics of growth simply by working at the appropriate temperature. Also as will be evident below, neutron small angle scattering provides important advantages in following the growth of precipitates in bulk. Three particular advantages have been exploited. (1) The range in scattering vector $\mathbf{Q}(\mathbf{Q} = (4\pi \sin\theta)/\lambda)$ which it is possible to study includes the region around $\mathbf{Q} = 0.005$ Å^{-1} which generally falls between the scope of X-ray small angle scattering and light scattering measurements; (2) the low absorption of neutrons even at long wavelengths (~10 Å) allows the easy investigation in transmission of a bulk glass which is heated directly in the neutron beam; and (3) the precipitating phase (an aluminium titanate solid solution) is rich in titanium atoms, and the negative scattering length of titanium ensures that there is good scattering contrast between the precipitate and the host silicate glass. All the experiments were carried out at the Institut Laue-Langevin on the D11 spectrometer[5].

The general form of the scattering curves obtained is shown in Fig. 1; these curves were obtained on a glass nucleated by a pretreatment at 720 °C for 10 h. SANS is negligable immediately after nucleation and corresponds to the zero-time curve of Fig. 1. On heating *in situ* at 835 °C, SANS increases rapidly with the growth of the particles giving sufficient scattered intensity to allow the scattering curve to be followed every few minutes.

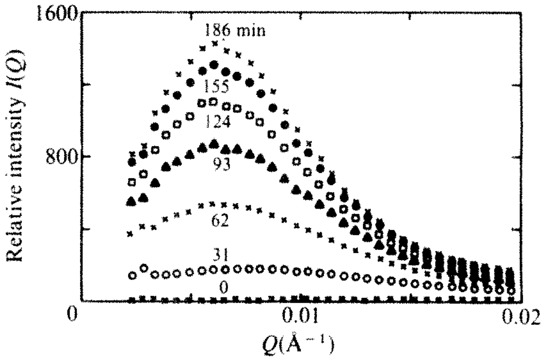

Fig. 1 Small angle neutron scattering curves from cordierite glass heated at 835 °C after nucleation pretreatment at 720 °C for 10 h.

We emphasise some features of these curves which are characteristic of the particle nucleation condition before the onset of growth. The dominating feature of the curves is the pronounced maximum ($Q_M = 0.007$ Å^{-1}) with the intensity falling towards zero at low Q. Even at the earliest times for which the precipite is very small, the maximum is apparent and the position remains stable during the growth period. The maximum is due to an interference effect between particles for which the spatial distribution is partly ordered. Similar effects are observed for the decomposition of alloys[6]. From the position of the maximum one obtains a rough estimate of the mean distance between the precipitates ($l \sim 2\pi/Qm$) of 900 Å corresponding to a precipitate density of about 10^{15} cm^{-3}. We follow the development of the precipitates using Guinier plots on the high Q side of the maximum. The form of the scattering curve is, however, distorted by the interference term, so that the values obtained in this way are only approximate. Within the limit of validity $QR_g \leq 1.2$ the scattering function $\overline{SQ}$ is related to the radius of gyration R_g according to $\overline{SQ} = \exp(-Q^2/R_g^{2/3})$ and $R_g = (^3/5)1/2R_s$, where R_s is radius of a spherical particle.

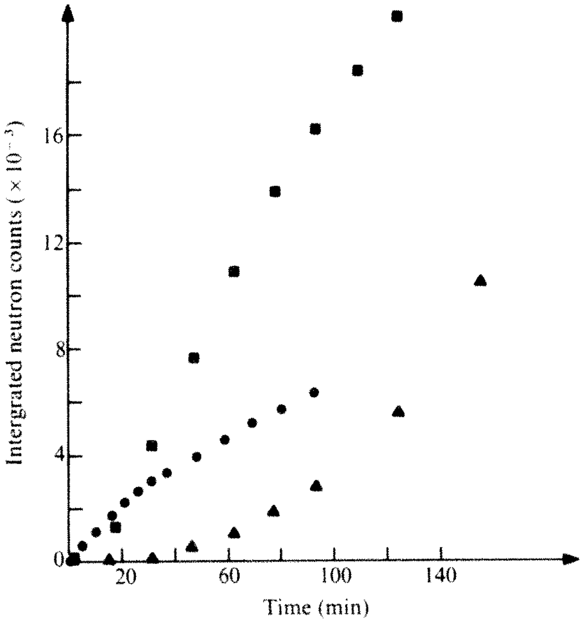

Fig. 2 Growth of integrated SANS intensity with time at 835 °C for different nucleation conditions. ■, 720 °C for 10 h; ●, 720 °C for 20 h; ▲, no nucleation treatment.

0028-0836/79/0277–0366$01.00

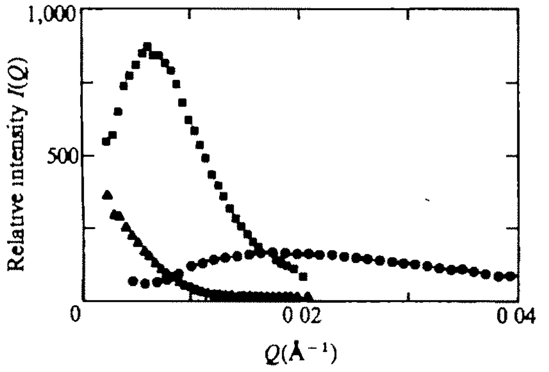

Fig. 3 SANS from cordierite glass heated for 90 min at 835 °C for different nucleation conditions. ■, 720 °C for 10 h; ●, 720 °C for 20 h; ▲, no nucleation treament.

For the glass discussed above, R_s increases from 40 Å after 2 min to 210 Å after 180 min at 835 °C. There is an initial period of about 10 min (the induction period) where the SANS intensity increases very slowly, followed by a longer period (100 min) during which a rapid linear increase of intensity with time occurs before the rate slowly declines (Fig. 2). The intensity is a function of the volume of the precipitate and the contrast between the precipitate and the glassy matrix, which increases during growth as a result of the depletion of titanium ions from the glass. Indeed we observe that the intensity is proportional to the square of the volume of the precipitate which leads to the result that the scattering contrast is directly proportional to the degree of depletion of the glassy matrix.

When the nucleation pretreatment time is varied, different scattering behaviour occurs (Fig. 3). Allowing no nucleation time we observe an induction period of ~50 min (Fig. 2), when weak scattering occurs in the low Q region. Guinier plots here indicate the presence of particles of 600–800 Å. A second linear region at higher Q in the Guinier plot corresponding to a mean particle size of about 200 Å develops with time until it dominates the plots after 100 min, but there is no indication of an interference maximum in the scattering curve. The average particle size achieved is of the order of 500 Å, but the Guinier plots become nonlinear after long growth times, characteristic of a large distribution of particle sizes, or of irregular shaped particles.

If the nucleation time is increased to 20 h at 720 °C there is no induction period, but we observe a linear growth of intensity with time during the first 30 min before the rate declines slightly (Fig. 2). A broad but easily observed interference maximum is detectable after 5 min of growth, now centred at $Q = 0.018$ Å^{-1}, corresponding to an inter-particle spacing of 350 Å or a particle density of $\sim 2\times 10^{16}$ cm^{-3}. The particle sizes are now much smaller, being detectable at 20 Å and growing to only 55 Å after 100 min. The crystallised glass in this case is transparent, whereas non-nucleated and nucleated at 720° for 10 h are respectively white opaque and blue translucent after the crystallisation at 835 °C.

The significance of the results is that they provide information about the state of nucleation immediately before the growth. For the pretreatment of 20 h at 720 °C the immediate growth in SANS shows the existence of a large population of stable nuclei larger than the critical radius R_c. These are particles for which the Gibbs free energy will decrease with increasing size favouring immediate growth once the temperature is raised to give enough thermal energy for diffusion. The immediate presence of a maximum, however, indicates that the nuclei are present in an ordered manner, and gives a measure of the nucleation density. As the initial particle size is considerably smaller than the inter-particle distance, it is unrealistic to consider that the spacial order is due to development of extended excluded regions around the particles caused by depletion of growth material in the glassy matrix or by an Ostwald ripening mechanism[7]. Such mechanisms would only generate an interference peak in the advanced stages of growth of the precipitate, so it is necessary to adopt an alternative hypothesis in which the homogeneous quenched glass undergoes structural changes during nucleation which lead to an enhanced probability that subsequent nucleation proceeds in an ordered or partly ordered manner.

The behaviour after a heat treatment time of 10 h is typical of many of the heat treatments we have performed, where an induction period is observed in the growth kinetics. It is reasonable (after Walton[8]) to consider that this period is composed of three parts

$$t = t_i + t_n + t_g$$

where t_i is the time to obtain a steady state in the cluster distribution, t_n is the time required for nucleation, and t_g is a part of the growth period where the particles are too small to be detected. Thus t_g does not influence the form of the growth curve, but simply makes the early part unobservable and so can be neglected. If we equate t_i with the time to develop concentration fluctuations, and t_n with the time to grow nuclei to the critical size then we can explain our results so far. During 10 h nucleation at 720 °C we develop metastable fluctuations or clusters in the glass, but fail to grow nuclei above R_c. On heating to 835 °C the microstructure is such that nuclei develop rapidly in only 10 min. The nucleation density is, however, much lower than after 20 h at 720 °C as many subcritical nuclei will redissolve at the higher temperature. This is shown by comparison of the size of the particles formed, although in no case have the particles reached the limiting radius. For the glass with no pretreatment we expect a small nucleation density arising from the imperfect quench from high temperatures. The results indeed show rapid growth of a few nuclei which disappear out of the lower end of our Q window, followed by the formation and growth of new nuclei at the end of a long induction period. In this case the induction period will include the time to establish a glass microstructure at 835 °C, followed by growth of the nuclei to the critical size. However, any nuclei present immediately begin to grow, generating a depleted region which limits the development of other nuclei. As we observe, the nucleation density is therefore smaller and disordered, and a wide particle size distribution in the crystals is seen.

These results show the scope of SANS in examining nucleation and growth in glasses. The technique we used, which as far as nuclei are concerned is analogous to a photographic development process, demonstrates that there are important structural changes taking place at temperatures below the glass transition temperature (T_g for this glass is 760 °C). In the cordierite glass system the possibilities for further examination of the time-temperature zone of nucleation are obvious. SANS in our view is the most promising way to explore the effects of the numerous catalysts (such as TiO_2, ZrO_2, and P_2O_5) which are employed in glass ceramic systems. Although in the present experiment we have been aided by the scattering contrast provided by titanium, SANS methods should be generally applicable to the study of nucleation and precipitation in glasses and probably other inorganic systems. Full details of the present work will be described elsewhere.

We thank Gernot Kostorz for assistance, also Pilkington Brothers Ltd, for the glass.

The structure of α′-copper phthalocyanine and its susceptibility to radiation damage

CHANGES in electron diffraction patterns are a very sensitive monitor of the radiation damage experienced by a periodic specimen under observation in an electron microscope. In the study of α′-copper phthalocyanine reported here, we have recorded the diffraction pattern of the a^*–c^* plane as irradiation proceeds, and from its behaviour we have been able to confirm the structure of the undamaged crystal and put realistic limits on the electron dose allowable if molecular images of a given resolution are to be obtained. We can also confirm the suggestion of Isaacson *et al.*[1] that the heavily damaged material forms a regular matrix, and that this matrix has approximately the same structure as that observed in previously published molecular images of this specimen[2,3].

The electron diffraction pattern produced by a crystalline specimen comprises a regular array of spots, the intensity of each being proportional to the square of the amplitude of the electron wave function at that point in the diffraction plane. If, somehow, the correct phase can then be ascribed to each amplitude, the wave function is completely determined and its form in any other plane may be calculated. In particular, the Fourier transform of the diffraction plane wave function may be calculated, and within the validity of the kinematic approximation, this is proportional to the electrostatic potential of a unit cell averaged over all the lattice sites. In the case of a perfect crystal this is identical to the potential of any individual cell, but as irradiation proceeds the system becomes a mixture of damaged and undamaged molecules. In these circumstances, although the Fourier transform of the wave function at the diffraction spot positions is still proportional to the average potential, this quantity need not be identical to the potential of any individual cell. Nevertheless, the concept of the average unit cell of such a mixture is a useful quantity. This is because the electron dose experienced by a radiation-sensitive specimen must be limited if there is to be a high probability that the molecules under observation are undamaged. When recording a high resolution image in these conditions very few electrons contribute to each picture element and so the intensities recorded will be substantially affected by statistical fluctuations. Thus in most studies of molecular images there must be some sort of periodic averaging to recover structure from these noisy intensities, and so the behaviour of the average unit cell with increasing irradiation dose is a valid guide to the molecular detail we can hope to obtain. Furthermore, electron diffraction patterns are less affected by lens aberrations than are electron images, and directly useful diffraction patterns may be recorded with very much smaller irradiation doses. We have therefore used diffraction patterns rather than images to study these crystals from the virtually undamaged state to that where no appreciable long range order remains.

Thin crystals of α′-copper phthalocyanine were produced by epitaxial deposition on a heated (300 °C) KCl substrate and were subsequently covered by a thin evaporated coating of carbon. The carbon film–crystallite combination was then floated off on water. Electron diffraction patterns were obtained in a JEOL JEM 100C electron microscope and recorded on Kodirex crystallographic X-ray film. Subsequent densitometry was carried out on a Joyce Loebl flat bed densitometer, the intensities of each spot in the pattern yielding a quantity proportional to the square of the amplitude of the corresponding Fourier component of potential.

To determine the required diffraction plane wave function we must supply phases to each of these measured amplitudes. We proceeded by noting that the structure of platinum phthalocyanine has been determined and that the resemblance between its X-ray powder photographs and α′-copper phthalocyanine have led to the suggestion that their structures are similar[4]. However, recently published molecular images of α′-copper phthalocyanine have indicated that the molecules, whose shape is not in doubt (Fig. 1*a*), may be rotated with respect to those in platinum phthalocyanine[2,3].

To identify the correct orientation we examined these two possibilities to see which was consistent with our single crystal electron diffraction pattern data. Initially, we considered the structure isomorphous with platinum phthalocyanine and by assuming suitable theoretical potentials for each atom, calculated the theoretical diffraction plane wave function for this model. An experimental wave function was then constructed by combining the measured amplitudes with the calculated phases. If the phases are correct then the Fourier transform of this wave function should yield a structure very like that of the model. The resulting reconstruction (Fig. 1*b*) is indeed very similar to the model, individual atoms being resolved in many instances. When the orientation of the model is rotated through angles as small as 1° and the new phases combined with the measured amplitudes, agreement between model and reconstruction is less, and for rotations $>5°$ parts of the molecule becomes unrecognisable in the reconstruction. Thus we are confident that α′-copper phthalocyanine has the same structure as platinum phthalocyanine and that the molecule is orientated with respect to the lattice as shown in Fig. 1*b*.

As irradiation proceeds individual molecules become damaged and deform. Although we do not expect them to do so in an identical way we would expect that because the molecules were originally centrosymmetric, the average unit cell of a mixture of damaged and undamaged molecules will also be centrosymmetric. As such, the phases attributable to each diffraction spot will still be 0 or π. Furthermore, as irradiation proceeds we would not expect to see a discontinuous change in the phase from 0 to π which would produce a change in the sign of the Fourier component of potential. Rather we would expect either a gradual diminuation of the spot intensity to zero followed by a reappearance of the spot corresponding to a phase change, a gradual variation to a new value without falling to zero implying no phase change, or a gradual diminuation to zero corresponding to loss of all long range order of that periodicity. In our study, although many intensities did vary appreciably, none passed through a zero before reappearing. Thus we believe that the original phases should be used in each of the Fourier reconstructions of the partially damaged crystals. Using this procedure we have recovered the average electrostatic potential after various electron irradiation doses (Fig. 1*c*, 1*d*).

As we can see, the behaviour is quite consistent with an increasing number of molecules becoming seriously disrupted, losing long range order of high resolution detail, but retaining some order at low resolution. The structure observed in (Fig. 1*d*) is strikingly similar to previously published[2,3] molecular images and provides experimental confirmation that the technique is valid. In the diffraction pattern corresponding to this reconstruction, all but the first three orders of spots have completely faded and the remaining intensities are relatively stable. We conclude that this averaged unit cell corresponds to the radiation-resistant matrix of damaged molecules suggested by Isaacson[1], where although seriously disrupted, the material retains some periodic detail.

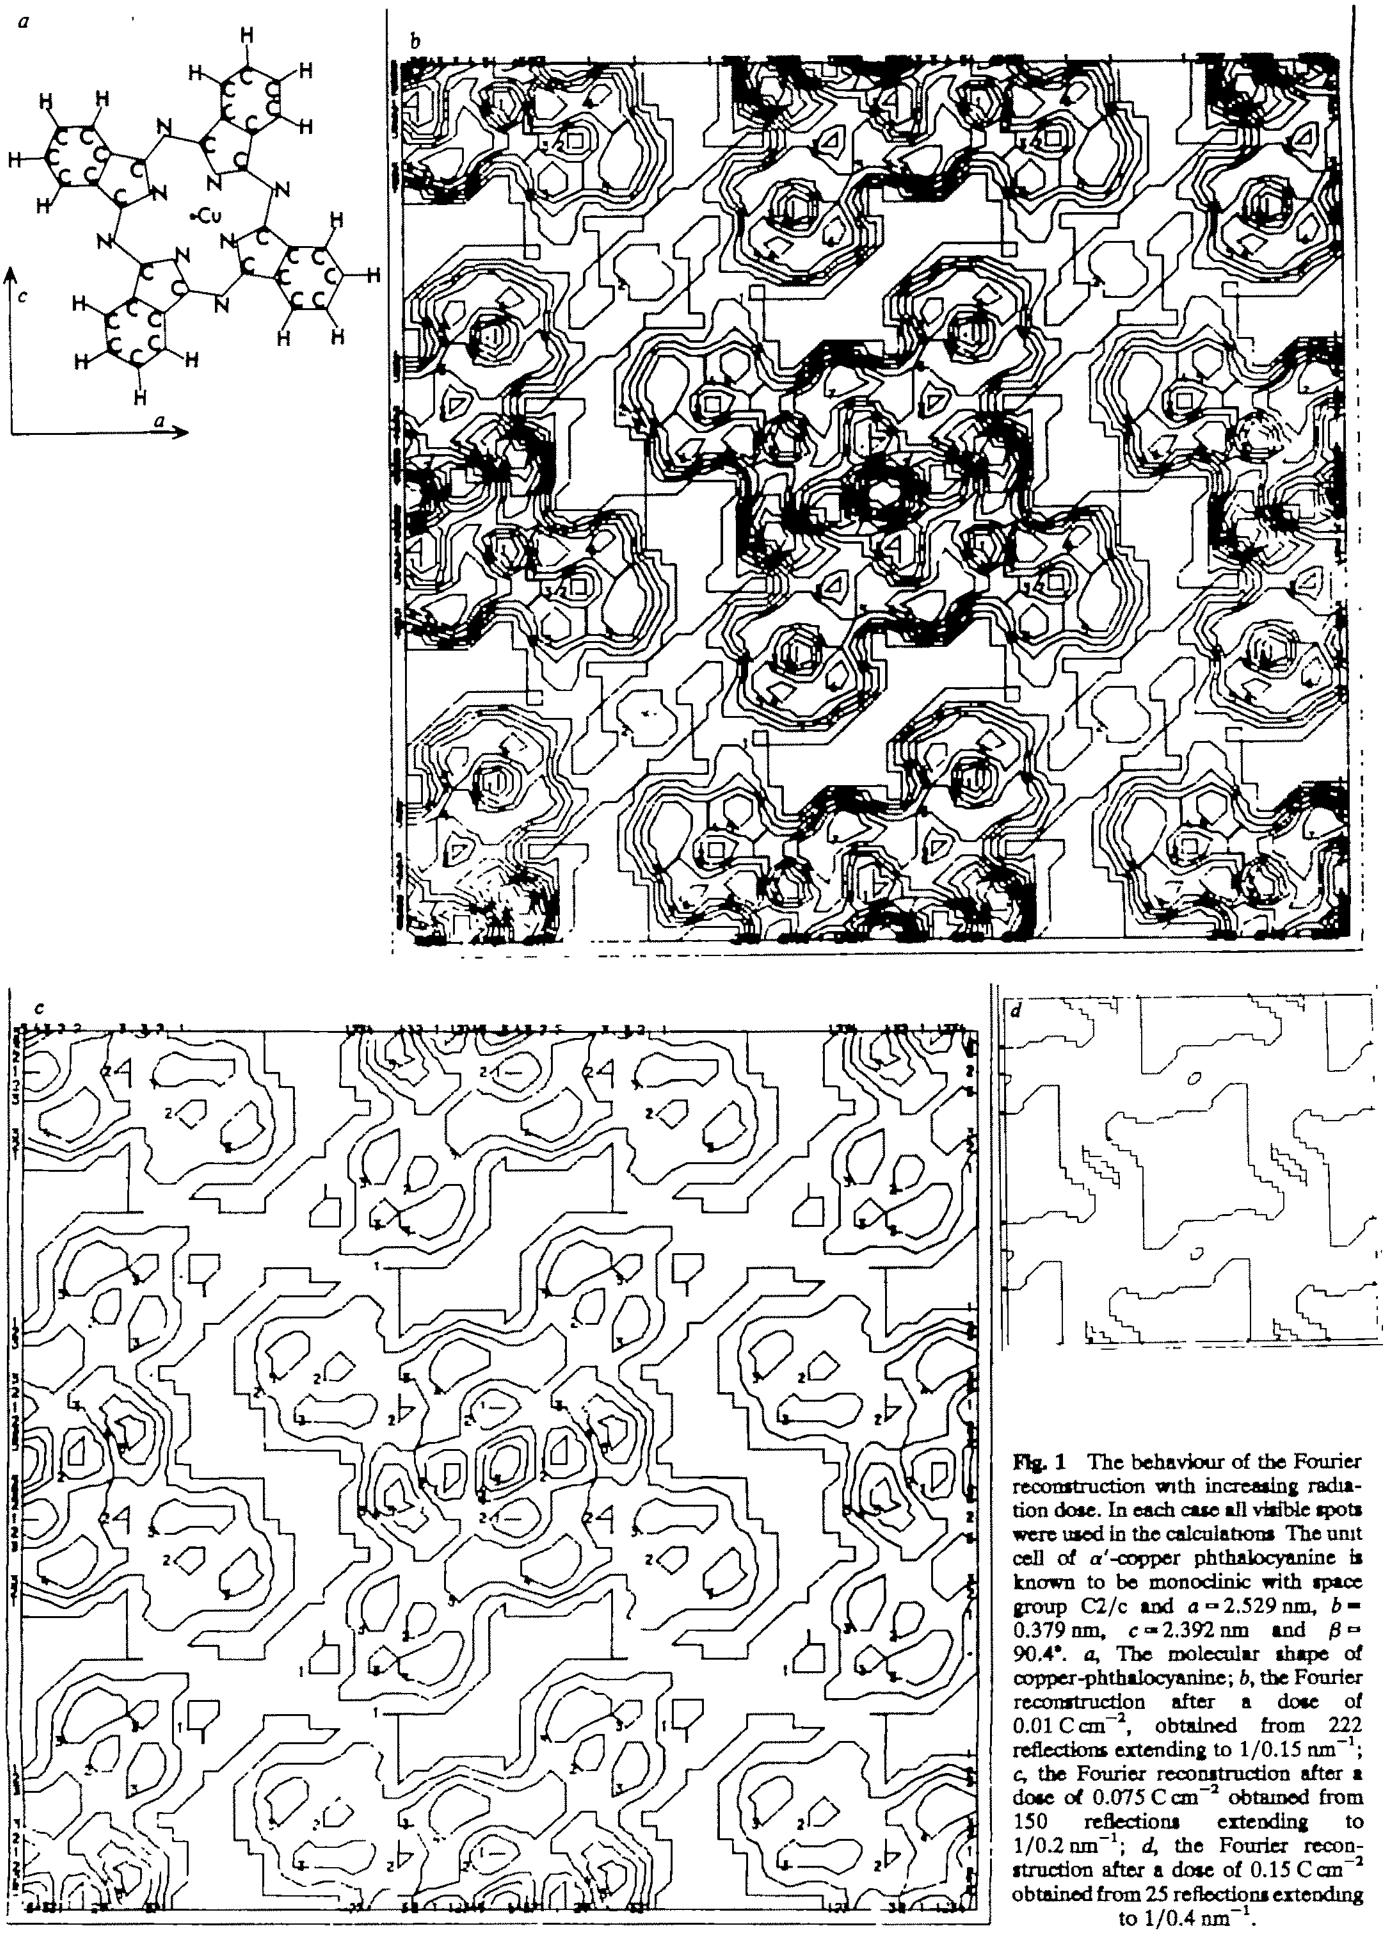

Fig. 1 The behaviour of the Fourier reconstruction with increasing radiation dose. In each case all visible spots were used in the calculations The unit cell of α'-copper phthalocyanine is known to be monoclinic with space group C2/c and $a = 2.529$ nm, $b = 0.379$ nm, $c = 2.392$ nm and $\beta = 90.4°$. *a*, The molecular shape of copper-phthalocyanine; *b*, the Fourier reconstruction after a dose of 0.01 C cm^{-2}, obtained from 222 reflections extending to 1/0.15 nm^{-1}; *c*, the Fourier reconstruction after a dose of 0.075 C cm^{-2} obtained from 150 reflections extending to 1/0.2 nm^{-1}; *d*, the Fourier reconstruction after a dose of 0.15 C cm^{-2} obtained from 25 reflections extending to 1/0.4 nm^{-1}.

From the behaviour of these reconstructions we suggest that for high resolution detail to be preserved the irradiation dose should be $<0.01\ \mathrm{C\ cm^{-2}}$ and that the presence of periodic detail in images of this and similar materials recorded with greater values correspond increasingly to damaged material.

Radiation pressure and 'aether drag' in a dispersive medium

ARNAUD[1] has pointed out that there should be no transverse 'aether drag' in an artificial dielectric consisting of parallel plane conducting elements, where the product of the phase and group velocities of electromagnetic waves should be equal to the square of the velocity of light *in vacuo*. This agreed with the formula derived by Player[2] and Rogers[3], who for some important examples of aether drag showed that the Fresnel drag coefficient $(1-1/n^2)$, where n is the refractive index, should more precisely be replaced by $(1-1/n_\phi n_g)$, where n_ϕ and n_g are respectively the (phase, or normal) refractive index and the 'group' refractive index.

The same factor $(1-1/n_\phi n_g)$ seems to arise in the division of momentum into what may be described as 'electromagnetic' and 'mechanical' components when a packet of radiation enters a dispersive medium[4]. If the momentum of the packet *in vacuo* is p, the total momentum associated with the packet in the medium is $n_\phi p$, of which a portion p/n_g corresponds to the 'electromagnetic' momentum and $n_\phi p(1-1/n_\phi n_g)$ to mechanical momentum bodily in the medium. Thus, for any medium in which $n_\phi n_g = 1$ as in a wave guide or artificial dielectric, the mechanical component of momentum is zero, and the total momentum should be entirely electromagnetic.

The foregoing conclusion was derived by a thought-experiment involving a modified Einstein light-box to which were applied the relationship $E = mc^2$ and the consideration that actions inside a closed system cannot change the position of its centre of mass. Ginzburg and Ugarov[5] have come to the same conclusion in a more detailed consideration of a particular case, where they conclude: "it is curious that for an isotropic (dispersive) plasma with $n^2 = 1-(\omega_0^2/\omega^2)$, the equation G^M (the electromagnetic momentum) $= G^A$ (the total momentum) holds." For it is also true that for such a plasma $n_\phi n_g = 1$.

The Ginzburg and Ugarov conclusion applies to a medium where the electrons are free, and not when they are bound as in a dispersive non-conducting solid. In that case some of the wave energy is carried as potential energy of electron displacement, and there is a consequent sharing of momentum. With free charges there is no corresponding potential energy of mechanical displacement from fixed centres and so it is at least plausible that there is no mechanical momentum drawn from the wave momentum. A common factor in the artificial dielectric and the plasma is the presence of free (inside the conducting elements) rather than bound electrons.

A corollary of the absence of mechanical momentum when $n_\phi n_g = 1$ seems to be that any medium satisfying this condition will also exert no 'aether drag'. A moving plasma in free space should therefore conform to this expectation, a conclusion also reached by a more detailed argument for the particular case of a cold plasma by Ko and Chuang[6].

A moving plasma can exert an aether drag, in apparent contradiction to the foregoing conclusion, when the plasma consists of moving carriers inside a semiconductor moving parallel to the direction of the light, as observed by Moss, Burrell and Hetherington[7]. I thank M. A. Player for resolving this contradiction—the solution lies in the fact that the plasma is now embedded in a medium of refractive index different from unity, with its faces in motion relative to the frame of reference in which the plasma is stationary. Such a situation, as pointed out by Einstein[8] and Landsberg[9], gives a modified Doppler shift, and when this is allowed for, a result consistent with Moss's observation is obtained.

An interesting variation of Moss's experiment would be to look for an aether drag effect when the free carriers in a semiconductor are moving transversely to the direction of the radiation.

Plasma convection in force-free magnetic fields as a mechanism for chemical separation in cosmical plasmas

DURING the past two decades, progress in space research has forced us to abandon the earlier idea of a cosmical plasma as being a homogeneous medium. Filament formation and chemical separation are two important phenomena that are often observed in cosmical plasmas and illustrate the importance of inhomogeneity. An average composition from the Sun's atmosphere used to be taken as a standard when expressing cosmic abundancies in general. Numerous observations, however, of the chemical composition in the solar wind from *in situ* measurements and from lunar soil and meteorite samples, indicate a great variability in these ratios[1]. The proton to α-particle flux ratio for solar flare energetic particle events varies widely between and within events[2]. Recent observations show that this variability is connected with the flare process itself and the earlier history of the flare, rather than propagation effects between the flare site and the observer. Some local chemical differentiation mechanism in the preflare history of the specific active region is probably responsible for the composition of the emitted, energetic particles. The phenomena of filamentation and chemical separation may be coupled, as in the presence of a temperature gradient, the plasma convection associated with filamentary structures provides an effective means of selective transport. The general principles of this mechanism are described here. These principles may be important not only in solar flares but in many other cosmical plasmas where force-free fields and thermal gradients occur.

Typical filamentary structures, such as prominences and solar flares, can often be pictured as helical twisted magnetic flux tubes[3–6], where the magnetic field is approximately force free. The electric current flows almost in the direction of the magnetic field.

0028–0836/79/0277—0370$01.00

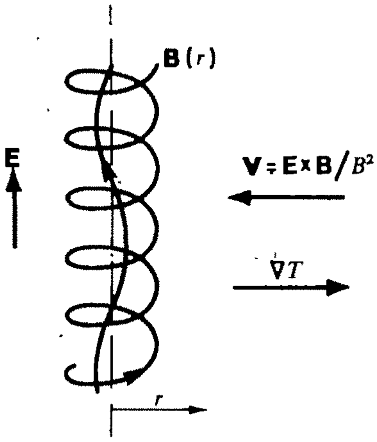

Fig. 1 General form of the magnetic field line pattern in a force-free axisymmetric filamentary structure. The ionised components of the plasma are convected inwards with a velocity V across a temperature gradient ∇T.

Consider for simplicity an axisymmetric case with a force-free helical magnetic field **B**, and a homogeneous electric field **E** applied parallel to the axis of the filament, to drive the current (Fig. 1). We assume that we have a transparent filament where the temperature decreases towards the axis of the filament due to a preferential cooling by radiation of the densest regions.

Under the influence of electric and magnetic fields the ionised component of the plasma will drift inward from the surroundings towards the centre of the filament with a velocity $\mathbf{V} = \mathbf{E} \times \mathbf{B}/B^2$, directed radially inwards. Some steady state models of filamentary structures, where this inward drift of plasma is balanced by an outward diffusion of neutrals, have been described elsewhere[7].

This $\mathbf{E} \times \mathbf{B}/B^2$ convection is a very efficient process for collecting material to form the filament. This is true, even if the process is slowed by collisions, because as long as the particles are charged they are forced to drift inwards.

If the plasma is partially ionised—as in part of the solar atmosphere and many other cosmical plasmas—a temperature gradient will cause the radial transport to be different for elements with different ionisation potentials.

The most abundant elements of a cosmical plasma can be divided into groups of roughly equal ionisation potentials as follows: element, (approximate ionisation potential): He, (24 eV); H,O,N, (13 eV); C,S, (11 eV); Fe,Si,Mg, (8 eV).

Consider, for example, a case where the ambient plasma consists of hydrogen and helium in some initial proportion $p_0 = \{n(\mathrm{H}) + n(\mathrm{H}^+)\}/\{n(\mathrm{H_e}) + n(\mathrm{H_e^+}) + n(\mathrm{H_e^{2+}})\}$ where $n(\ )$ denotes the density of the element within the parentheses. In the configuration considered the ionised components of the plasma will drift inwards and experience a temperature decreasing with radius. When the charged particles have drifted so far that the local temperature is well below the ionisation potential of helium, the rate of recombination of ionised helium is considerable. The neutral helium produced is unaffected by the electric and magnetic forces that drive the ionised particles inwards. On the other hand, the hydrogen is still almost fully ionised, and is therefore still under the influence of the inward force. The protons will continue to drift inwards until they reach a radius where the temperature is well below the ionisation potential of hydrogen. Thus helium and hydrogen will be preferentially deposited in different regions (which may partly overlap). Compared with the composition of the initial ambient plasma, the above process will result in an enrichment of hydrogen in the inner parts ($p > p_0$) and of helium in the outer parts ($p < p_0$).

Although this discussion has considered a very simple configuration, the process works under very general circumstances. Any $\mathbf{E} \times \mathbf{B}/B^2$ convection in a multicomponent plasma will tend to separate elements of different ionisation potentials whenever spatial temperature gradients cause the different elements to leave (or join) the convection preferentially in different regions of space. Note also that the $\mathbf{E} \times \mathbf{B}/B^2$ convection can be a very rapid transport process compared with diffusion. (The latter will in general tend to counteract the separation. However, in thermally inhomogeneous, partly ionised plasmas, even diffusive processes can lead to non-homogeneous chemical distributions[8-10].)

In the case of the flare process, the separation mechanism discussed above might be of importance for the great variability in composition observed. Because an equilibrium composition requires some time to get established in this way, an individual flare or the first flare in a series of flares will show a different composition of particles than that of a successive flare, which shows a composition characteristic of the partially re-established equilibrium. However, here the main purpose is to emphasise the existence of a separation mechanism intimately linked to force-free filamentary structure, and to describe the basic operative principles and potentially wide applicability.

I thank Professor H. Alfvén for discussions, and Professor C.-G. Fälthammar for reading the manuscript.

Persistence of rainfall anomalies in the central Pacific

THE behaviour of the atmosphere and ocean in the equatorial Pacific region, involving the 'Southern Oscillation' and '*El Nino*' phenomena, has been the subject of many studies[1-5]. Attention has been drawn to the notable persistence of anomalies for a year or more, the spatial correlation of sea surface temperature (SST), rainfall and pressure over large areas, and the strong correlation between atmospheric and oceanic features. Two types of mechanism may explain these phenomena and why they are so marked in that region: (1) thermal inertia, for example, some region of the ocean has a large capacity for heat storage, and the heat takes many months to build up or become depleted; (2) positive feedback, for example, if stronger winds in some region favour colder water, and colder water favours stronger

Table 1 Stations used in rainfall index

Data for 1941–78.

winds, then even if the thermal inertias of both features are such that their time constants are a month or less, anomalies can persist for many months[6]. New evidence is given here to support a feedback explanation.

Monthly rainfalls at the stations listed in Table 1 were obtained. A preliminary eigenvector analysis indicated that seasonal rainfalls at all these stations vary coherently. The monthly values were transformed by calculating cube-roots, to reduce the otherwise dominant influence of the wettest months on the analyses. Using the transformed data, each individual monthly value was then expressed as a percentage of the mean for that month over the datum period 1948–67. Finally, an index, *I*, was calculated for the period 1941–69 as the mean over stations 1–5, and for 1970–78 (when complete data for stations 1 and 2 were not available) as the mean over stations 3–6. Thus *I* is a series from which the annual variation has been removed, and in which no time smoothing has been performed.

Part of the series *I* is shown in Fig. 1*a*. Its persistence is remarkable, especially by comparison with almost any other meteorological series. Lag correlations for 1–6 months are, respectively, 0.79, 0.69, 0.56, 0.42, 0.31 and 0.20.

If the data are stratified by months, some interesting properties are evident. Table 2*a* shows that the variability of the index is least in April and then increases fairly steadily to 2.5 times its April value by November. Figure 2 shows that month-to-month persistence is quite strong throughout the year, and very strong during the period September–February. Also, there is notably strong persistence over several months from September to February, and weaker but still substantial persistence from June to the following March. Persistence is much weaker during March to June. The breakdown occurs at the season of lowest variability; the greatest persistence occurs in the months of highest variability. These facts indicate that anomalies that develop initially around May to August tend not only to persist, but even to amplify. The amplifying property is emphasised by the regression coefficients of each month's index on the previous month (Table 2*b*), which are greater than unity in some months. Thus the regional rainfall has the following remarkable property: given the September anomaly, the best estimate of the October anomaly is an anomaly of the same sign and more extreme.

The pattern of negative lag correlation on the right side of Fig. 2 indicates a slight tendency for the anomaly to reverse in sign from one September–December to the next, and also a tendency for the sign in January–March to be reversed in the June–December of the following year.

In a typical year the rainfall anomaly in the region changes as follows. In April the anomaly is, in percentage terms, not very great. During May to August, either a dry or a wet regime tends to become established, with a steadily increasing tendency to persist. The regime during July and August is then likely to persist for many months, often until the following March. In particular, the regime in September is very likely to persist at least until January. If August is wet (dry), the next three months are not only likely to continue wet (dry), but also are as likely as not to be wetter (drier). From November to March the absolute value of the anomaly tends to decrease, and the regime shows an increasing tendency to break down. A new regime then tends to develop during April to August. The new regime is more likely than not to be the opposite of that prevailing in the previous year, and there is a hint that in some years, the new regime starts to show itself by January.

Fig. 2 Lag correlations of I in each month with I in the subsequent months. For example, January with February is 0.82; January with March 0.73; April with the following April −0.08. Data for 1941–78.

These relationships have obvious direct value for statistical prediction. It will be particularly valuable to monitor the development of the anomaly during May to September.

These properties of the rainfall series strongly indicate that some positive feedback mechanism, with the strength of the feedback varying through the year, is operating. To support this statement, I will examine the behaviour of a synthetic variable A involved in a feedback relationship with a second variable B, with external forcing F acting on A, according to the model:

$$\frac{dB}{dt} = -k_A(B-A) \quad \text{and} \quad \frac{dA}{dt} = -k_A(A-qB-F)$$

When F is constant, this system tends to equilibrium if q is <1, and diverges if q is >1. When F comprises a random series, the solutions exhibit fluctuations that are stable if q is <1, and divergent if q is >1, a property noted by Hasselman[7]. Here we consider the system

$$\Delta B = -0.02(B-A)\,\Delta t$$
$$\Delta A = -0.08(A-qB-F)\,\Delta t$$

in which the unit of time is taken to be 1/50 month, so the time constant of $A(1/0.08)$ is a week, of B a month. F is the Markov series

$$F_k = 0.8F_{k-1} + E_k$$

where $[E_k]$ is a series of random numbers, so F has a spectrum similar to that of weather fluctuations. In this model A always influences B, while the influence of B on $A(q)$ is given the values 0.4 in months 1–3, 0.8 (4–6), 1.3 (7–9) and 0.8 (10–12).

A sample of A is shown in Fig. 1b, and its statistical behaviour over 40 'yrs' is summarised in Table 3 and Fig. 3. The instability characteristic of months 7–9, when q is >1, takes the form of strong persistence, increasing variability, and regression coefficients near or exceeding 1.0. This behaviour is similar to that of the rainfall series I around October. Moreover, the general characters of the series I and A are similar. Closer similarity could be obtained by making appropriate changes to the constants in the model, but this has not been pursued. This comparison is sufficient to indicate that the behaviour of I can be explained as the result of a positive feedback relationship between two features with time constants of a month or less, in which the feedback is least around April and greatest around October.

For physical justifications, it must be shown that there are features whose mutual influences do have those properties. At present only a qualitative explanation can be offered. Rainfall in the equatorial central Pacific is least when the surface easterly winds there, that is, the Walker circulation, is strongest[1]. Therefore I probably represents an index of the Walker circulation. A stronger Walker circulation favours more upwelling of cold water along the Equator due to Ekman divergence, and also stronger advection of colder water from the south-east Pacific; at the same time, colder SST in the equatorial-east Pacific implies a stronger surface temperature gradient along the Equator, which would favour a stronger Walker circulation[8]. This combination of mechanisms implies positive feedback, which could explain the persistence in I. However, there are other mechanisms of interaction between the Walker circulation and the SST; for example, strong Walker circulation is associated with decreased cloud cover in certain areas, which would favour warming of the ocean. Further, as the Walker circulation interacts with other atmospheric and surface features, additional feedback relationships may be involved. Any or all of these feedbacks might vary through the year; for example, stronger Walker circulation might favour stronger surface winds over the Indian Ocean in one season (favouring surface cooling) and weaker winds in another (favouring warming). All such interactions need to be identified quantitatively before we can claim a complete physical explanation of the statistical properties of I.

Fig. 3 Lag correlations of A (output of the feedback model) in each month with A in the subsequent months. Data for 40 'years'.

We have shown that rainfall anomalies in the equatorial central Pacific have remarkably high persistence during part of the year. The temporal patterns of lag autocorrelations and variability are readily explainable in terms of a positive feedback relationship in which the strength of the feedback is a function of season. Around October the feedback is so strong that the system displays the potential for 'runaway' behaviour. The feedback probably operates between the Walker circulation (on which the rainfall depends) and the SST, but studies of all the interactions between the Walker circulation and surface features will be necessary to confirm this quantitatively. Prospects are good for successful prediction; the index should be monitored particularly during May to September, because anomalies that develop then have a strong tendency to persist until the following February–March.

I thank colleagues for comments. This research has been supported by the NSF as part of the North Pacific Experiment of the International Decade of Ocean Exploration.

Acoustic attenuation in Lake Tanganyika

THE Lake Tanganyika acoustic attenuation experiment of April 1970 (ref. 1) was the second of two lake experiments designed to help identify the cause of the low-frequency attenuation anomaly in seawater by providing comparative freshwater data. Although the Lake Tanganyika results showed no evidence of the anomaly, the attenuation was unaccountably large. Recent laboratory experiments have shown that the anomaly arises mainly from a chemical relaxation involving boric acid[2]. We have been investigating pertinent chemical equilibria using the acoustic resonator technique[3] and we have encountered another chemical relaxation–absorption in seawater[4] that is evidently also responsible for the Lake Tanganyika results.

Table 1 Chemical relaxation data

	North Atlantic	Lake Tanganyika	Lake Superior
	(concentrations in mg mol l^{-1})		
Mg	53	1.7	0.1
ΣCO_2	2.5	7.2	0.5
Ca	10	0.3	0.3
SO_4	27	0.03	0.03
$B(OH)_3$	0.5	0?	0?
Temp. (°C)	4	23	4
*p*H	8.0	8.5	7.4

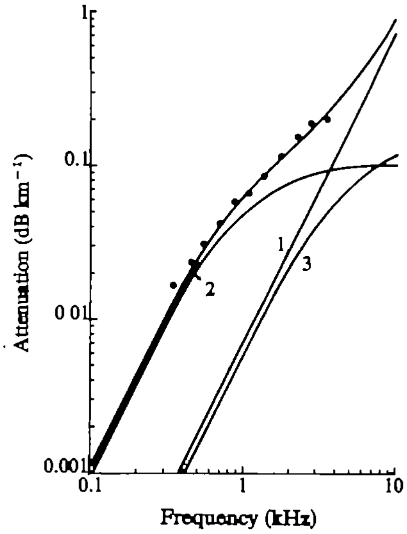

Fig. 1 Three relaxation components of sound absorption in the North Atlantic Ocean: 1, $MgSO_4$; 2, $B(OH)_3$; and 3, Mg/CO_2. The relaxation curves are of the form $\alpha_n = A_n f_n f^2/(f^2+f_n^2)$, where α_n is the component absorption coefficient (dB km^{-1}), A_n is a constant depending on the parameters, f is frequency, and f_n is the relaxation frequency. the top curve is total absorption and points are experimental field data.

Figure 1 shows the relative contributions of the three chemical relaxations in seawater, specifically in the North Atlantic Ocean deep sound channel. The newly discovered third relaxation involves magnesium and carbonic acid with calcium acting to reduce the component absorption by roughly a factor of two. Like that of the boric acid relaxation, the absorption varies as 10^{pH} for pH < 9. (The nominal pH range in the world ocean is

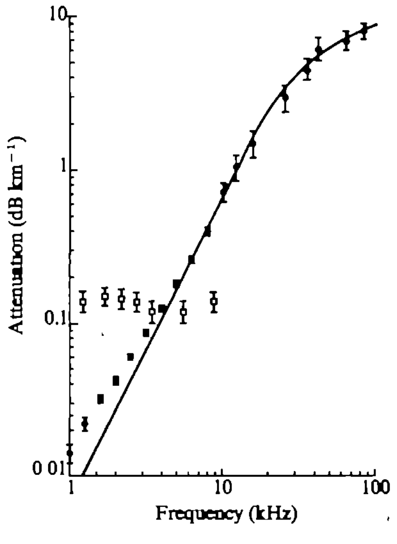

Fig. 2 Comparison of Lake Tanganyika (●) attenuation and synthetic lake water (○) results. The synthetic lake water constituents are $MgCl_2$, $NaHCO_3$ and $CaCl_2$ with appropriate values for Lake Tanganyika from Table 1. The *p*H is adjusted with NaOH. (Na and Cl concentrations are irrelevant.) The solid line is a relaxation curve-fit to the resonator data with relaxation frequency 40 kHz. The excess Tanganyika attenuation at low frequencies is believed to be caused by scattering. Lake Superior (□) also shows a frequency-independent scatter attenuation which is much greater because the water is shallower and the sound channel consequently weaker. Similarity to the $B(OH)_3$ absorption curve of Fig. 1 originally led us to the hypothesis that the seawater anomaly might also be present in freshwater which was, of course, contradicted by the Lake Tanganyika experiment.

7.7–8.3). The relaxation frequency varies from 4.5 to 40 kHz in the temperature range 0–30 °C.

Concentrations of the essential chemical components in the North Atlantic Ocean, Lake Tanganyika, and Lake Superior (the first lake experiment)[5] are given in Table 1 together with temperatures and *p*H values on the respective sound channel axes. Figure 2 shows a comparison of the Lake Tanganyika attenuation and the laboratory resonator results with synthetic lake water. The solid line is a relaxation–absorption curve-fit to the resonator data. The small systematic excess seen in the Tanganyika data at low frequencies is believed to indicate an additional frequency-independent attenuation arising from diffusive scattering by random temperature inhomogeneities within the sound channel[6]. This mechanism is evidently solely responsible for the results of Lake Superior where the scatter loss is greater because of the weaker sound channel and the chemical absorption is negligible[7].

We conclude that the acoustic attenuation in Lake Tanganyika is due primarily to a chemical relaxation–absorption involving magnesium and carbonic acid with a calcium moderator. Although neither the reaction nor even the chemical species involved are yet known, the results may be of wider interest than simply acoustical because of potential chemical and biological implications.

Glaciation in Bolivia before 3.27 Myr

AN *in situ* layer of ignimbrite overlies till near the base of a thick sequence of glacial and fluvioglacial sediments at La Paz, Bolivia. Two radiogenic age determinantions on the ignimbrite gave results of 3.27 ± 0.14 and 3.28 ± 0.13 Myr. We show here that this indicates that climatic cooling in the Southern Hemisphere was sufficiently severe to produce a mountain ice cap over part of the tropical Andes before 3.27 Myr and that these mountains had probably become tectonically elevated to about their present altitude by that time.

One of the most complete vertical sequences of late Tertiary to Recent strata in Bolivia is in the suburbs of La Paz where streams draining westwards and southwards from the Cordillera Real have cut gorges over 800 m deep into a variety of sediments (Fig. 1). Composed mainly of fluvial and fluvioglacial gravels, sands, silts and clay and till, with minor beds of lacustrine sediments and a layer of volcanic ash flow debris (ignimbrite), the deposits have been studied in most detail by Dobrovolny[1]. Table 1 summarises his interpretation of the sequence, which contains evidence of four major glacial episodes following the deposition of the La Paz Formation, a series of deposits of late Tertiary–early Quaternary age; the ignimbrite was erupted after the first glaciation.

A more recent revision of the area by Servant[2] subdivides the deposits rather differently but retains a similar sequence of four glaciations occurring after the La Paz Formation. One important departure from Dobrovolny's interpretation is the identification of two different beds of ignimbrite, one in the upper part of the La Paz Formation but before the first glaciation and a second resting on deposits of the first glaciation. He identifies these as the Chijini and Sopari ignimbrites respectively but does not describe them in detail; they appear only in his composite diagram of Plio–Quaternary stratigraphy (Fig. 2, on page 324 of ref. 2). Servant's analysis of the latter was based partly on his identification of four denudation surfaces in the north-west part of the Altiplano; he estimates that the oldest formed before the first glacial expansion from the Cordillera Real. A further proposal is that the oldest surface is the same age as an ignimbrite (Formación Peréz[2]) found in the western Altiplano 100–150 km west and south-west of La Paz. As this ignimbrite has an age of 2.5 Myr (Evernden *et al.*[3]) the implication of Servant's work is that the first glaciation occurred after that date. These conclusions are based upon rather tenuous stratigraphical interpolation over large distances, however, and had Servant dated the two ignimbrites appearing in his stratigraphical diagram a more definitive statement could have been made concerning the age of his first glaciation.

I have recently encountered a small but new section in the northern suburbs of La Paz exposing a bed of ignimbrite overlying what appeared to be a layer of till at an altitude of ~3,900 m. The exposure is located in the gorge of a small left-bank tributary of the Rio Choqueyapu or Kaluyo (Fig. 1), the same valley in which Dobrovolny observed his 'Chijini' ignimbrite overlying the oldest till.

The deposit beneath the ignimbrite is a very indurated layer of unsorted clasts up to 30 cm in size held in a compacted clay-like matrix; it averages 2 m in thickness. Out of three samples of 25

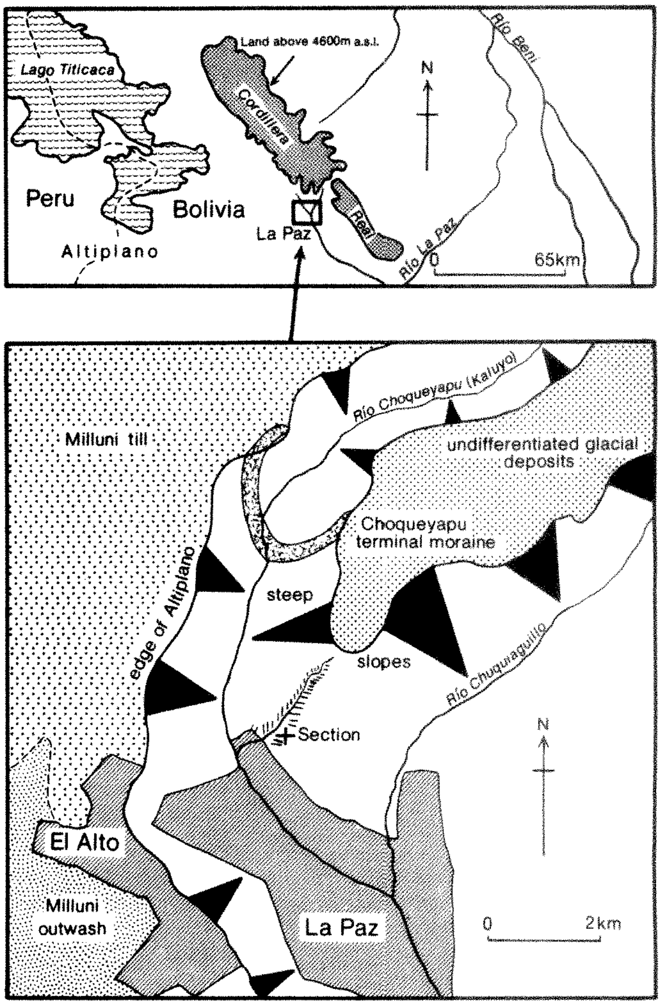

Fig. 1 Maps showing the location of the La Paz area in Bolivia and the site of the new section.

Table 1 Summarised description and interpretation of deposits in the La Paz districts of Bolivia*

	Period	Formation label	Description	Weathering	Maximum thickness (m)
Holocene	Post glacial	—	Landslide, mudflow, alluvium, etc	—	—

* After Dobrovlny

stones, 70% were sub-angular in shape and 30% angular; several were well faceted and bore the polish and striations normally associated with glacial abrasion. More than 50% of the sampled stones were granitic, the rest being mainly hard sedimentary rocks; a few basic igneous stones were also present. Three samples of 25 stones with distinct long axes (ratio >2 : 1) were measured to see if there was a preferred alignment of the clasts. Fifty-six per cent of all stones were orientated within the arc of 120–140°, 92% lying between 120° and 170°; in other words a strongly preferred orientation that could be roughly classified as NW–SE or SE–NW. The former alignment would be entirely in keeping with the direction of ice flow at the base of an ice mass spreading outwards from the adjacent Cordillera Real (Fig. 1). The lower two-thirds of the deposit is a purple-grey colour whereas the upper third has been oxidised to a red-brown colour.

Because these characteristics and the stratigraphical position of this deposit are very similar to those of the lowest till identified by Dobrovolny ~5 km further up-valley, it is interpreted here as the same deposit. Dobrovolny considered this till and associated fluvioglacial sediments to have been much more profoundly oxidised than any of the subsequent overlying Pleistocene deposits and suggested that a considerable length of time elapsed before the eruption of the Chijini ignimbrite.

At the new section a bed of ignimbrite 2–3 m thick rests on the weathered upper surface of the indurated till. This volcanic deposit is a well known phenomenon of the La Paz district, outcropping as a distinctive single layer 2–15 m thick in the main gorges. Dobrovolny observed the ignimbrite above the oldest till in upper reaches of the valley but noted that it directly overlies the preglacial La Paz Formation elsewhere. A sample of the ignimbrite submitted for a radiogenic age determination gave the results shown in Table 2. Two radiogenic ^{40}Ar analyses were performed on a pure biotite sample prepared from the ignimbrite. There is a close agreement between the two determinations, and McIntyre, who did the radiogenic analysis, considered that the measured age of 3.27–3.28 Myr is a good estimate of the volcanic event which produced the deposit.

Table 2 K–AR Analyses of biotite in ignimbrite, La Paz

K (wt %)	Mass (mg)	^{40}Ar* ($\times 10^{-7}$ SCC g^{-1})	^{40}Ar*/^{40}Ar$_T$	Age* (Myr)
7.11	104.9	9.037	0.222	3.27±.14
	91.7	9.070	0.243	3.28±.13

* Decay constants from Steiger and Jager[4].

The main implications of these age determinations concern the age of the La Paz Formation, the approximate timing of the tectonic elevation of the Cordillera Real, and the onset of full glacial conditions in these mountains.

Opinions on the age of the La Paz Formation (which is up to 500 m thick) have varied from Miocene to Quaternary, the uncertainty arising because of the lack of fossiliferous and other datable remains. Dobrovolny, however, after summarising all previous work, concluded that the scant fossiliferous evidence (the vertebrates *Scelidothereum* and *Parahipparion*) obtained from middle beds of the formation indicate a Lower Pleistocene age for these strata whereas the non-fossiliferous and coarser upper beds grade conformably into the first glacial outwash deposits. He tentatively assigned an Upper Pliocene age to sediments composing lower parts of the formation lying beneath a truncated deeply oxidised horizon which separates them from the middle beds. The fossiliferous evidence is so dubious, however, that it cannot be used as compelling evidence for determining the absolute age of the associated strata. If the radiogenic age of 3.27 Myr for the overlying ignimbrite is correct, then the entire sequence of the La Paz Formation is of Pliocene age.

As pebbles of granite from plutonic intrusions in the Cordillera Real are contained in lower beds of the La Paz Formation the mountains must have become tectonically elevated and eroded some time before 3.27 Myr. This agrees with Petersen's[5] view that the latest phase of Andean uplift began in the Pliocene after the formation of the Puna plantation surface in Peru, Bolivia and Chile.

The spatial extent of till sheets (including the earliest) and piedmont moraines along western flanks of the Cordillera Real suggest that a mountain ice cap built up and discharged coalescent outlet glaciers 15 km beyond the foothills during periods of full glaciation. The earliest till layer, overlain by the dated ignimbrite, thus indicates that a substantial mass of glacier ice was present over these mountains more than 3.27 Myr ago. It is tempting to equate this glacial event with the first large-scale glaciation of the southern Andes dated at 3.5 Myr by J. H.

Mercer[6]. Such correlation may be reasonably valid because Dobrovolny observed that the oldest till is intensely oxidised, suggesting a considerable time interval before the deposition of the overlying ignimbrite. Because till of the penultimate ice cap glaciation, exposed for possibly more than 100,000 years, is weathered to only a shallow depth, the intense alteration of the oldest till may well indicate a time interval of the order of 0.23 Myr. The first Bolivian glaciation would therefore most logically fit with the first Patagonian event.

Oxygen isotope and palaeomagnetic evidence from the Northern Hemisphere led Shackleton and Opdyke[7] to suggest that the last lengthy period of stable sea level (global) and low ice volume (global) ended ~3.2 Myr ago. Mercer[8], however, has since drawn attention to his evidence from Patagonia which shows that ice age cold prevailed in middle latitudes of South America 0.3 Myr earlier. This corresponds with recent work in the Barents Sea area of the Northern Hemisphere by Kvasov and Blazhchishin[9] suggesting the existence of an ice sheet there 3.5 Myr ago. The deposits in Bolivia indicate that climatic conditions in the Southern Hemisphere had become sufficiently severe more than 3.27 Myr ago to allow the formation of an ice cap over a mountain range within the tropics. If the altitude of the Cordillera Real (present peaks between 5,000 and 7,000 m) has not been changed substantially by tectonic activity within the past 3.5 Myr, then the equilibrium line of the tropical ice cap was low enough to discharge outlet glaciers down to 3,900 m above present sea level. There is therefore an accumulation of evidence, deriving from polar regions[9,10] and from middle and tropical latitudes of the Southern Hemisphere, which strongly suggests that the cold period of 3.5 Myr ago may have caused the first global large-scale glaciation of the Late Cainozoic ice age.

I thank the NERC for financial support and Ingos Alvaro Fernandez and Antonio Michel of the Bolivian Geological Institute for field assistrance, Dr I. M. Munro for the biotite sample and Dr R. M. McIntyre for the radiogenic analyses.

A stratified water column environmental model for the type Kimmeridge Clay

GALLOIS has reported the widespread occurrence of coeval coccolith limestones and oil shales in the Kimmeridge Clay of southern England and Lincolnshire[1,2]. From the association of these limestones with oil shale horizons he suggested that the organic content of the Kimmeridge Clay was largely derived from phytoplankton blooms whose decay produced the temporary anaerobic bottom conditions necessary to preserve organic matter. However, comparisons with similar Quaternary sediments in the Black Sea and Mediterranean has led us to report here that phytoplankton blooms were not the cause, but rather a symptom of widespread anaerobic bottom conditions, and that preservational factors rather than productivity are the major control on the accumulation of black shales. We believe that the fine grained clastic-bituminous shale–oil shale–coccolith limestone lithologic association characteristic of the type Kimmeridge Clay can be attributed to the vertical movement of the $O_2:H_2S$ interface in a temporarily stratified water column.

Figure 1 summarises the main features of the oil-shale and coccolith-rich portion of the type succession of the Kimmeridge Clay. The whole sequence was apparently deposited below wave base with only rare and indirect evidence of current activity, such as occasional low angle contacts exhibited by coccolithic streaks within sapropel rich horizons. The Kimmeridge Clay lithologies, with the exception of the early diagenetic dolomites, show a cyclic distribution pattern involving lithologies A–B–C–D (as on Fig. 1). Lithological changes through each cycle are accompanied by changes in faunal content. The clays (A) contain a fairly abundant low diversity macrofauna of small, thin shelled benthonic bivalves, plus a nektonic element including ammonites, fish and reptiles; the plankton includes dinocysts, coccoliths and rare acritarchs. In the bituminous shales (B) the macrofauna is similar to that of the clays, but it tends to occur only at discrete horizons.

In the oil shales and coccolithic limestones (C, D) benthonic fossils are rare or absent, and the non-carbonate organic content consists dominantly of amorphous sapropel with above average proportions of terrigenous palynomorphs[3,4]. High concentrations of Cu, Ni, Mo, P, I and Br[5] are associated with the organic matter. Preliminary scanning electron microscope studies have shown that the coccolithic laminae often contain well preserved coccospheres. Framboidal (probably early diagenetic) pyrite is ubiquitous in the coccolithic limestones, occurring in close association with organic membranes and palynomorphs.

The Quarternary sediments of the Black Sea and eastern Mediterranean basin also demonstrate an association of fine grained detrital, bituminous and coccolith rich lithologies (see Fig. 2 and legend for a summary of their principal lithologies). Radiometric dating of these sequences has enabled them to be matched with the climatic and physical oceanographic data for the Quarternary[7–9], providing an insight into conditions that prevailed at the time of their deposition which we have applied to the Kimmeridgian.

The basal part of the Black Sea sequence (see Fig. 2: Unit Three) contains no marine macrofauna, and its dinocyst assemblage suggests that salinities of about 7‰ prevailed[11]. Unit Two was deposited in marine conditions for it contains marine dinocysts, and marine sapropelic organic matter predominates over terrestrial humic material[10,11]. The organic matter is associated with pyrite framboids and high concentrations of trace elements[12]. The dark laminae within the coccolith oozes of Unit One have recently been interpreted as the products of seasonal mass mortality of the photosynthetic bacteria that live just below the $O_2:H_2S$ interface in the Black Sea[13]. Cooling of the surface waters during the winter decreases the stability of the low salinity surface layer and enables turbulent mixing processes to reach down to the $O_2:H_2S$ interface. The subsequent oxygenation of these lower waters causes mass mortality of the anaerobic bacteria. During the descent of the dead bacteria, the elemental sulphur which they contain probably acts as a nucleus for the formation of pyrite framboids within the water column[13]. Unit Three was deposited in a freshwater environment which was replaced by marine conditions between 10,000 and 7,000 yr ago when the post glacial eustatic rise caused the Mediterranean to spill over the Bosphorus Sill into the Black Sea. This produced a strong salinity-based stratification, and increased the productivity of the surface waters, the combined effects of which resulted in the stagnant bottom waters becoming rapidly anaerobic leading to the deposition of Unit Two. The $O_2:H_2S$ interface rose rapidly from the sea floor until about 3,000 yr ago[14], (see Fig. 2) when it reached a level where convective or turbulent mixing processes could provide its nutrients to the euphotic zone and hence stimulate the coccolith blooms which produced Unit One.

0028–0836/79/0277—0377$01 00

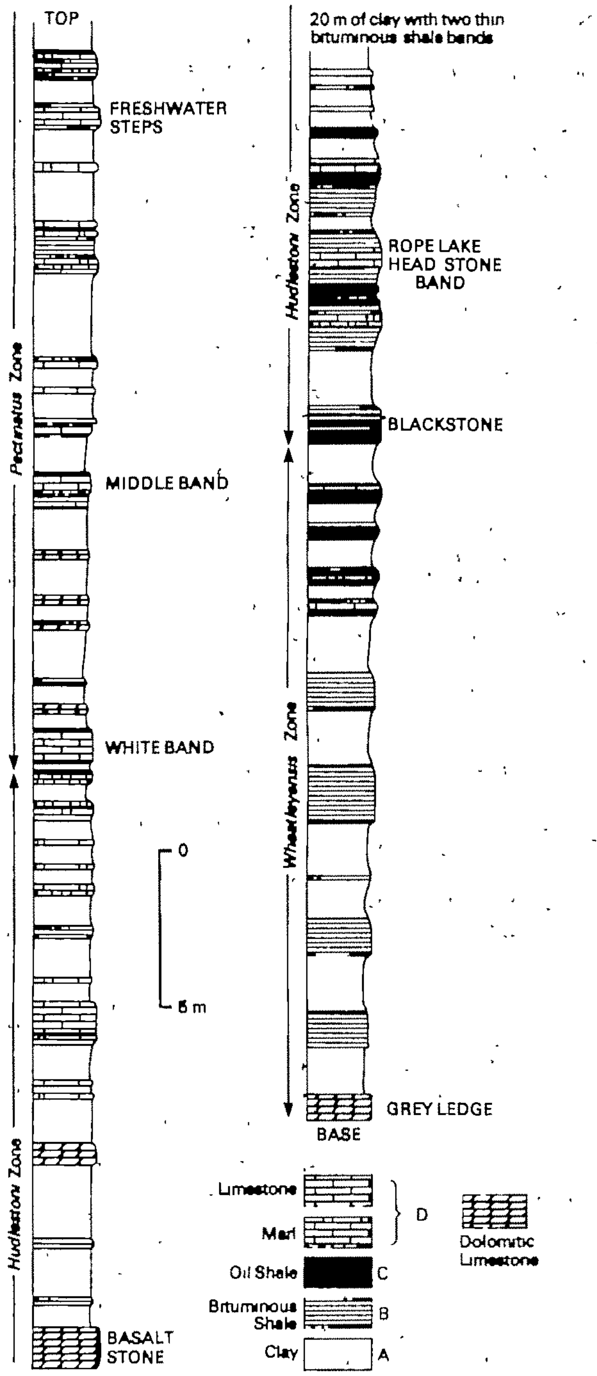

Fig. 1 A log of part of the type section of Kimmeridge Clay exposed in Kimmeridge Bay, Dorset. A, Clays—dominantly composed of illite, with minor silt sized material, up to 10% organic matter (predominantly amorphous sapropel); and ≤2% pyrite. B, Bituminous shales—similar composition to the clays, but higher organic content (≤30%). C, Oil shales—containing up to 70% organic matter. D, Coccolithic limestones—two varieties occur, one homogenised by bioturbation (for example, Rope Lake Head Stone Band), the other showing microlaminations of alternating dark coloured sapropel rich material and light coccolithic layers. Dolomites consist of a microcrystalline mosaic of ferroan dolomite, with amorphous kerogen either as dispersed fragments or discontinuous laminae (~0.25 mm thick). They formed over an extended period from early diagenesis onward by replacement of a pre-existing lithology[6].

The best documented sapropelic sequences of the eastern Mediterranean are those of the Nile Cone[8,16,17], but similar deposits occur throughout the basin[15]. The sapropel sequences are between 30 and 50 cm thick, and are developed between basal terrigenous (turbiditic) sediments and overlying calcareous hemipelagic sediments; the principal lithological components are shown in Fig. 2. They occur below a present day water depth of 550 m, and are best developed in the distal parts of the Nile Cone. Olausson[18] has developed a widely accepted depositional model for the eastern Mediterranean sapropels. The post-glacial amelioration of climate (which significantly altered the balance between evaporation and precipitation[9,15]) coupled with the effects of freshwater overspill from the Black Sea, resulted in a strong halocline which reduced the efficiency of vertical mixing processes and led to the formation of anaerobic bottom water. The simultaneous transgression also caused large amounts of clastics to be trapped on the widened shelves[8], so that there was minimal clastic dilution as well as enhanced preservation of organic matter.

The Quarternary examples imply that the Kimmeridgian sequence: clay–bituminous shale–oil shale–coccolith limestone may reflect the ascent of the $O_2:H_2S$ interface in a stratified water column. However, it is likely that the bottom water was just oxygen depleted for much of the time and did not always contain free H_2S. There are no indications of abnormal salinity in the type Kimmeridgian succession, and so dissolved oxygen was probably a more critical factor in determining the nature of faunal assemblages. The low diversity, thin shelled benthonic bivalve assemblage containing large numbers of small individuals, and the large planktonic component of the fauna are characteristic of low dissolved oxygen situations (~1.0 ml per litre O_2, ref. 19). The small, thin-shelled, dominantly shallow infaunal bivalves are also characteristic of soft 'soupy' mud substrates, their morphology representing an adaptation to flotation within the sediment[20].

Figure 2 summarises the environment of deposition we envisage for each of the main Kimmeridge Clay sediment types. The clays were deposited under oxygenated bottom conditions below normal wave base, partly by hemipelagic settling and partly from low density suspensions. As 75% of the bivalves are articulated, any currents must have been slight, but the occurrence of infaunal species, apparently on bedding planes (as seen also in the Oxford Clay[21]) suggests that at least some exhumation by gentle currents occurred. The bituminous shales formed during periods of fluctuating aerobic/anaerobic conditions with a consequent preservation of greater amounts of organic matter, and the restriction of macro-benthos to discrete horizons. The oil shales were formed in predominantly anaerobic bottom conditions with only very rare current activity and minimal clastic sedimentation. They mark an intermediate phase in the upward progression of the $O_2:H_2S$ interface. The higher proportions of miospores in the oil shales[3,4] (also seen in the Quaternary sapropels[22]) and the sparsity of dinocysts probably indicate a low level of plankton productivity. The coccolith limestones mark the maximum development of anaerobic bottom water in the Kimmeridgian water column. At this time the top of the H_2S zone had migrated to a level where seasonal convective processes could provide its nutrients to the euphotic zone and there stimulate a coccolith bloom. In the upper part of the *Hudlestoni* Zone and the lower part of the *Pectinatus* Zone (see Fig. 1) there are many cycles in which the oil shale is missing but the coccolith limestone is present. Interpretation in terms of our model suggests a shallower depth of water than that lower in the sequence (where there are relatively thick oil shales), because in this case, once the bottom became anaerobic the $O_2:H_2S$ interface would take less time to rise to the thermocline and conditions suitable for oil shale formation would have been short lived. In the modern Black Sea, the most characteristic micro-laminated coccolith oozes occur in the halistatic parts of the basin where there is only a weak annual bloom (in spring, associated with seasonal convection[23]) and minimal clastic

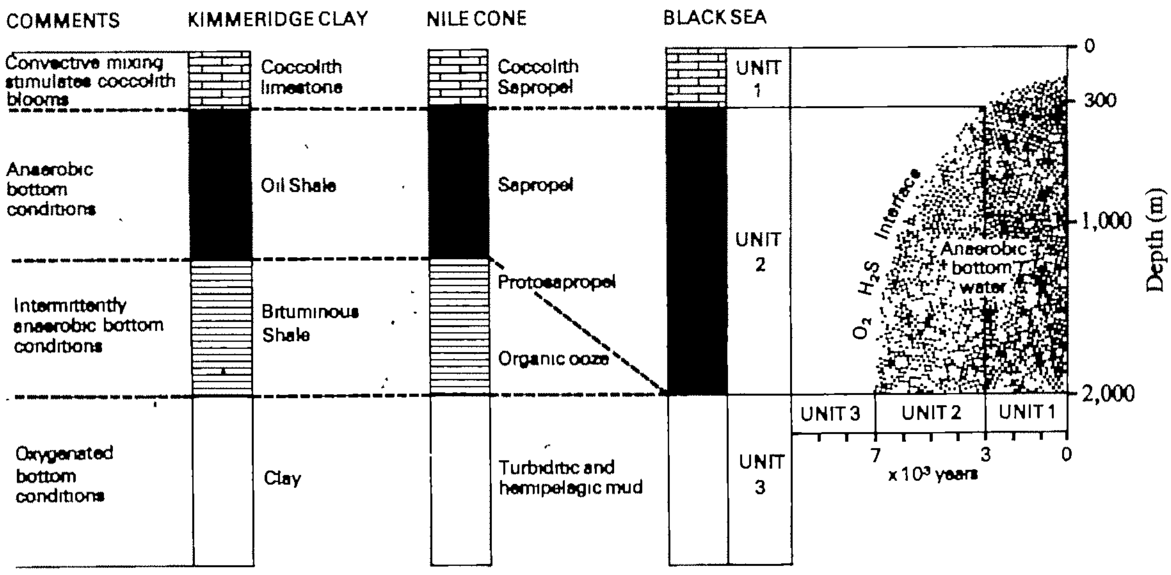

Fig. 2 Lithologies and environmental interpretations for the Kimmeridge Clay and Quarternary sequences discussed in the text. The sapropelic and coccolithic sequences of the Nile Cone and Kimmeridge Clay are interpreted in terms of the upward migration of the $O_2:H_2S$ interface documented in the Black Sea[14], culminating in convectional mixing of surface waters which stimulates coccolith blooms. Kimmeridge Clay lithologies are described in Fig. 1 and in the text. Nile Cone lithologies[8,16,17]: organic ooze—with up to 15% sand grade biogenic material; protosapropel—bioturbated sediment transitional between organic ooze and sapropel; sapropel—black, organic rich ($\leq$15%) sandy mud, including planktonic forams, authigenic pyrite. Some sapropels contain interlaminated coccolithic and terrigenous muds. Benthonic organisms are absent. Black Sea lithologies[7]: Unit One, biogenic calcareous ooze, with light coloured coccolithic laminae alternating with dark organic rich laminae of detrital clays; Unit Two, micro-laminated dark brown gelatinous sapropelic clay with $\leq$25% organic matter; Unit Three, partly homogenous and partly laminated light and dark banded lutites with interbedded turbiditic silts. Column sections are not to scale.

sedimentation. We believe that in this respect the Kimmeridgian is directly analogous. The preservation of the delicate laminations and coccospheres indicates that deposition was entirely by hemipelagic settling and that the bottom remained predominantly anaerobic during the deposition of the limestones. Dunn also believed, on the basis of pyrite distribution, that the coccolith limestones may have been deposited during the acme of anaerobic conditions[24].

Although the Kimmeridgian early diagenetic dolomites do not form part of the cyclothems, their development may be indirectly related to phases of watermass stratification. In the Mediterranean, precipitation of authigenic high Mg–calcites near the sediment surface shows an inverse relationship to the development of watermass stratification[25]. This pattern is also reflected in the Kimmeridgian succession, for dolomites tend to be more common where the oil shales and coccolith limestones are poorly developed (that is, below the *Wheatleyensis* Zone and above the *Hudlestoni* Zone).

The Quarternary examples used as the basis for our Kimmeridgian depositional model represent deep water oceanic environments, whereas the Kimmeridge Clay was deposited in a shallower shelf regime: we submit that this apparent paradox is not a serious challenge to our model. For example, below the $O_2:H_2S$ interface in the Black Sea the environment is remarkably uniform and it is doubtful if the bottom conditions would be greatly different whether it was 2,000 m deep, or just a few hundred metres deep. Thus, although our model cannot add anything to earlier estimates of the palaeo-bathymetry of the type Kimmeridge Clay, it does suggest that the deepest water conditions occurred during the deposition of that part of the sequence where oil shales are most abundant (the top of the *Wheatleyensis* Zone and the bottom of the *Hudlestoni* Zone).

The development of widespread stagnant conditions in North-west Europe during the Kimmeridgian was influenced by both palaeogeography and a rise in sea level. The Lower Kimmeridgian probably marked the maximum extent of the Jurassic shelf areas[26], and the increase in depth of the water column must have separated the mixed surface waters from the sea bottom, creating a stagnant, potentially anaerobic layer. At present, even relatively deep shelf seas are maintained in an oxygenated condition by wind driven currents and tidal mixing, and also by lateral circulation from the oceans. However, in comparison with its modern counterparts, the Kimmeridgian shelf sea was much wider, and the length of its oceanic (Tethyan) margin was small. Moreover, this margin was flanked by a carbonate platform in southern Europe which may have restricted the lateral shelfwards circulation of Tethyan water. The oxygenation of the internal shelf sea may, therefore, have depended largely on (seasonal?) convection and turbulent mixing in the surface waters, with the corresponding tendency for stagnation below wave base.

We can only speculate on what exactly controlled the cyclic ascent and decline of the $O_2:H_2S$ interface. Although in the Kimmeridgian the lithological response to stratification was almost identical to that in the Quarternary, it is clear that quite different mechanisms and controls were operative. The interpretation of the Quarternary examples revolves around the extreme climatic changes that occurred at the end of the last ice age, with glacial meltwaters and the land-locked nature of the basins playing a key role in the depositional model. Such an explanation is clearly incompatible with both Kimmeridgian palaeogeography and the more equable, sub-tropical climate of the period. Given this situation it seems probable that thermoclines, rather than haloclines, were the principal agents of water column stratification and stagnation in the Kimmeridgian. Quite small changes in local rates of subsidence, primary production, circulation pattern and climate may have combined to disrupt the fine balance between aerobic and anaerobic conditions to produce the short term cycles ($\geq$14,000 yr)[5] seen in the type Kimmeridge Clay.

Reduction of radiation damage in an electron microscope with a superconducting lens system

OBSERVATION of biological specimens at high resolution by electron microscopy is limited by radiation damage. In general, structural details of non-periodical arrangements can only be identified for doses of radiation up to 10^{-3} C cm^{-2}, corresponding to 63 e nm^{-2}, which restricts the resolution to approximately 2 nm (refs 1, 2). Many methods have been applied in an attempt to reduce radiation damage, including high voltage, high vacuum and specimen pretreatment. The most successful, however, was the reduction of the radiation dose, used for certain specimens with periodical structure, where the information could be obtained by computer-aided image enhancement from underexposed films[3]. In special cases, although it was possible to obtain information at high resolution, the specimen was partly destroyed[4]. The advantages of low temperatures were also investigated, but due to the lack of an adequate instrument, no agreement between the results could be obtained. Furthermore, little attention was paid to the significance of the dose rate at low temperatures. We now have in operation an electron microscope with a superconducting lens system in which the specimen is cooled to liquid helium temperature[5]. The most important features of this instrument are the high resolution, which allows the transfer of space frequencies corresponding to the inverse of 0.15 nm, the mechanical and electromagnetic stability (specimen drift 0.01 nm min^{-1}) and the ultra high vacuum around the specimen. These features are necessary for testing the effect of radiation damage. We report here experiments which demonstrate that radiation damage is considerably reduced at low temperatures in a dose rate-dependent manner.

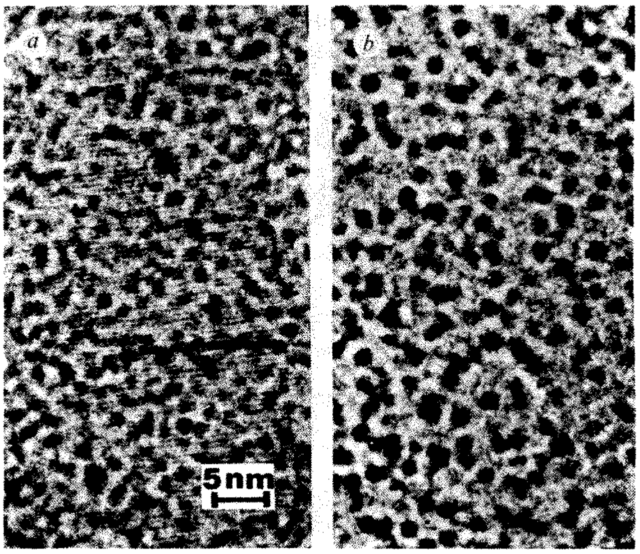

Fig. 1 Pt-stained murein or peptidoglycan, electron-optical magnification × 84,000. For *a* and *b*, respectively, exposure time was 110 and 3 s, dose rate was 3×10^2 and 10^4 e nm^{-2} s^{-1}, total dose during radiation was 3×10^5 and 1.5×10^6 e nm^{-2}, and estimated rise in temperature was <1K and $\geqslant 10$ K. The phase structures in *a* and *b* are not completely identical due to a defocus difference of about 10 nm.

One of the specimens used was murein or peptidoglycan (the rigid layer of a bacterial cell wall), specifically stained with Pt. According to a model published by Formanek[6], 0.45, 1 and 2 nm periodicities in the heavy-atom pattern of murein should be visible. The support was in most cases graphitic oxide, which shows very little phase contrast. In spite of extensive work, this structure has not been seen previously in the electron microscope.

Figure 1*a*, taken with a dose rate of 3×10^2 e nm^{-2} s^{-1} (0.005 A cm^{-2}) clearly demonstrates, even after a total irradiation dose of 3×10^5 e nm^{-2} (5 C cm^{-2}), the presence of 0.45-nm periodicities, which disappear as soon as the dose rate is increased to 10^4 e nm^{-2} s^{-1}(0.2 A cm^{-2}) (Fig. 1*b*). Light optical diffractograms of Fig. 1*a* show reflections corresponding to periodicities of both 0.45 nm and 1.0 nm. Such reflections were also detected on carrier-free murein.

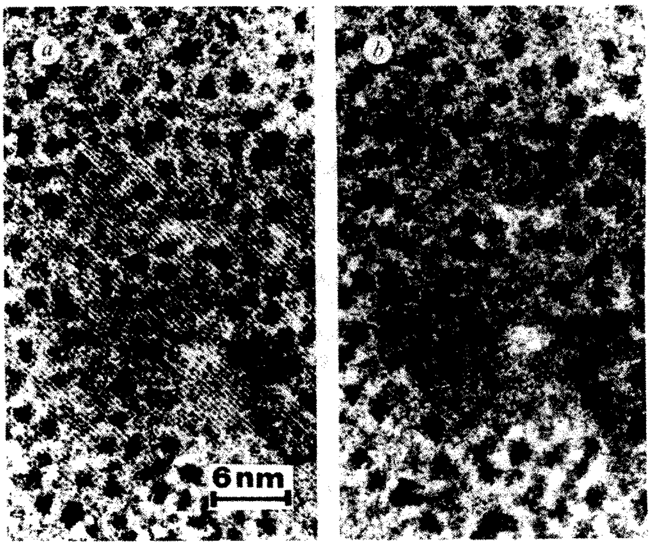

Fig. 2 Pt-stained polyhydroxybutyric acid, electron-optical magnification × 84,000. For *a* and *b*, respectively, exposure time was 120 and 16 s, dose rate was 3×10^2 and 5×10^3 e nm^{-2} s^{-1}, total radiation dose was 1.4×10^6 and 2.5×10^8 e nm^{-2}, and the estimated rise in temperature was < 1 K and $\geqslant 10$ K.

0028–0836/79/0277—0380$01.00

We also investigated a Pt-stained by-product of the murein preparation. Periodicities were clearly visible as long as the dose rate was kept below a certain critical value (Fig. 2*a*) and faded away when the dose rate was increased (Fig. 2*b*). We have assumed that the material is poly-β-hydroxybutyric acid, as this is the only possible crystalline organic contamination originating from the bacterial cell. In addition, a periodicity of 0.36 nm agrees with one of the main lattice distances of poly-β-hydroxybutyrate[7].

The observations that the conservation of the fine structure of the biological material strongly depends on the radiation dose rate we consider to be due to a temperature effect. The influence of the dose rate on the specimen temperature can be estimated[8]. For the compounds under discussion the chemical bonds are destroyed during the first exposure; however, the diffusion of the molecular fragments and especially the heavy atoms is prevented if the specimen is kept at a sufficiently low temperature. At the critical dose rate, the temperature is increased above the threshold value that permits diffusion. Comparison with the results obtained at room temperature shows that when specimens are observed close to liquid helium temperatures, damage to their biological fine structure is dramatically reduced.

We thank J. Dubochet for discussions.

Recent archaeological findings at the Sterkfontein site

UNTIL the present decade it was thought that the Early Stone Age of Africa consisted of two industrial complexes, the Oldowan and the Acheulian, the latter succeeding the former after a transitional phase. Well excavated and well dated Oldowan sites are known only from Eastern Africa, although Oldowan sites are reported from North and South Africa, and all known examples are older than 1.5 Myr (refs 1–4). The earliest manifestations of the Acheulian appear approximately 1.5 Myr BP (refs 5, 6) and continue until the Last Interglacial. Leakey has challenged the idea that the Acheulian represents a continuous development of the Oldowan in East Africa[1,7,8]. At Olduvai in Bed II she recognises two industrial complexes, which are said to represent two distinct cultural traditions, possibly produced by two different hominid taxa. These industries are the Acheulian and the Developed Oldowan. The criteria for defining the Developed Oldowan B have recently been revised and Leakey[7] now states that the morphology and technical features of manufacture of bifaces are the principal distinguishing characters between the two industries. The main technological distinction is that the Acheulian biface makers knew how to detach large flakes (>10 cm) while the Developed Oldowan hominids did not. As a result of this revised definition some of the assemblages at Olduvai originally defined as Developed Oldowan B have been reclassified as Acheulian by Leakey[7]. The problem of the Acheulian and Developed Oldowan can be stated as two alternative hypotheses. (1) Two cultural traditions began in East Africa approximately 1.5 Myr BP, each associated with a distinct social population over an immense span of time; possibly they were of different hominid taxa. Or (2), there was only one cultural tradition (industry), the Acheulian Industrial Complex, beginning about 1.5 Myr BP and marked by highly variable bifacial tools and relative frequency of artefact types; only one hominid taxon during any given period was involved. I have now made a comparative study of the Sterkfontein and Olduvai Gorge Bed II assemblages, which suggests that the Developed Oldowan B industry falls within the Acheulian Industrial Complex and therefore serious consideration should be given to dropping the former term.

To test the hypotheses four assemblages were selected for comparative analysis from Bed II at Olduvai Gorge, two defined Early Acheulian, EF-HR and TK Lower Floor (TKLF), and two defined Developed Oldowan B, TK Upper Floor (TKUF) and FC West Floor (FCWF). These assemblages were chosen because each is made up of material excavated from a single occupation floor, and therefore each represents a chronologically homogenous set of artefacts presumably produced by one social group of hominids. The other Bed II assemblages do not satisfy this criterion. Table 1 presents the shaped tool type percentages of the four assemblages, demonstrating clearly that the original criteria of the Developed Oldowan are no longer valid. TKLF, an Acheulian assemblage, has a high percentage of spheroids/subspheroids, the most varied light-duty tool component, and a low percentage of bifaces. This assemblage is considered Acheulian by Leakey[7] because of the technique of manufacture of the bifaces. The conclusions of the comparative study will be restricted to bifaces, the taxonomically critical type. Bifaces from the Sterkfontein site are shown in Fig. 1.

Nine attributes out of a larger set were selected to describe the morphological and technical features of the bifaces. The results are presented in detail elsewhere[9,10], including analysis of other artefact types. The application of non-parametric statistical tests (χ^2 and Mann–Whitney U test), measures of the coefficient of

variation, and computer assisted multivariate programs (average-linkage cluster analysis and discriminant analysis) were made of the five assemblages using the attribute values of the bifaces and resulted in the following conclusions. (1) The bifaces of the defined Acheulian assemblages were significantly different from those defined as Developed Oldowan B; (2) the Acheulian bifaces were longer, thicker, and had longer working edges; (3) the Acheulian bifaces were made significantly more often on large flakes (>10 cm); (4) the differences observed between the bifaces of the two industries were due to the difference in frequency of use of large flakes as the primary form for biface manufacture; and (5) the Acheulian bifaces display an equal degree of standardisation within assemblages as the Developed Oldowan B bifaces.

χ^2 Tests of the unmodified whole flakes demonstrated that large flakes in general were present significantly more often in the Acheulian assemblages. Because large flakes were present in the Developed Oldowan B assemblages, Leakey's assertion that culture tradition explained the inability of the Developed Oldowan B peoples to produce large flakes could not be immediately accepted. The alternative explanation of differential use of raw material was investigated.

Use of χ^2 tests showed that large flakes were produced significantly less often from quartz than from lava. Bifaces made from flakes and unmodified whole flakes were of quartz significantly more often in the Developed Oldowan B than in the Acheulian assemblages. These findings suggested that the basic difference between the Acheulian and Developed Oldowan B bifaces was the differential use of quartz and lava as raw material. In the absence of any other archaeological evidence, I suggest that the latter hypothesis be accepted—that is, that the Acheulian Industrial Complex, beginning about 1.5 Myr BP, was marked by highly variable bifaces and per cent frequency of artefact types. The term Developed Oldowan B should be dropped unless archaeological evidence can be produced to establish its independence from the Acheulian.

Using the BMDP 2M average-linkage cluster program on the CDC 6400 computer at the University of California, Berkeley, I found that the Sterkfontein bifaces clustered exclusively with the Acheulian bifaces of EF-HR, but that when assigned as ungrouped cases to the Olduvai assemblages in the discriminant analysis (SPSS program with Mahalanobis D^2 as the distance measure) they were more often grouped within the Developed Oldowan B of TKUF. The Sterkfontein bifaces were also found to be more highly standardised as assessed by the coefficients of variation of biface attributes and the discriminant analysis results[9,10]. A comparison of univariate frequency distributions of attributes of several different artefact types showed Sterkfontein to display no consistent patterns of similarity or dissimilarity with any particular assemblage of the Olduvai industries, but rather it presented an overall pattern of distinctive variability. I conclude that the Sterkfontein assemblage was Early Acheulian and that it displays characteristics that fall well within the range of those of the Acheulian complex of East Africa.

Jackal helpers and pup survival

BLACKBACKED jackals (*Canis mesomelas*) are one of the few mammalian species to have long-term pair bonds and to exhibit a tendency for some offspring to help in the provisioning and guarding of subsequent litters. Bonded pairs of adults were studied for 28 months over 3½ years at Lake Ndutu, Serengeti Plain, Tanzania. In the 15 litters observed, families with helpers had significantly higher offspring survivorship.

The blackbacked jackal is a small omnivore that typically occurs in brushland habitat[1–4]. Bonded pairs are territorial and both the female and the male mark and defend boundaries. Bonded pairs groom each other, hunt cooperatively[3], and share food. Parental care of pups is approximately equal. Both of them feed and guard the pups and the male regurgitates to his mate during the period of lactation. In all observed boundary fights the aggression occurred between same sex individuals. The territories form a mosaic with core territories in the centre of the *Acacia* sp. and *Balanites* sp. woodland surrounding Lake Ndutu, and peripheral territories adjacent to the short grasslands. Three of four pairs of blackbacked jackals identified in July 1974 still occupied approximately the same territories in February 1978. In August 1976 an additional five pairs were identified.

Eleven out of 15 litters observed had non-parent adult helpers. In 1976–77, five families were observed during two consecutive litters. In 1977, four of these families had helpers and the 'helpers' were pups from the previous year's litter. Thus with monogamous parents the helpers were full siblings to the litter of pups that they were caring for. Given this genealogy, the degrees of relatedness are as follows: parents to offspring, $r = 1/2$; helpers to full sibs, $r = 1/2$; parents to grandpups, $r = 1/4–1/2$ (dependent on degree of inbreeding); helpers to offspring, $r = 1/2$.

Presence of helpers may be partially dependent on the age of the parents. A pair with its first litter would not have any helpers. However, the survival of pups does not ensure the presence of helpers the next year. In 1976–77, four families had 12 surviving offspring. Of these, four stayed as helpers (1 per family). In the fifth family, four pups survived and none remained as helpers.

Helpers contribute food directly to the pups, and also regurgitate to the mother during the period of lactation. The percentage of observed regurgitations by helpers to pups varied from 18 to 32 within families. Helpers also contributed by guarding the pups while the parents were absent. Spotted hyenas do attempt

0028-0836/79/0277—0382$01.00

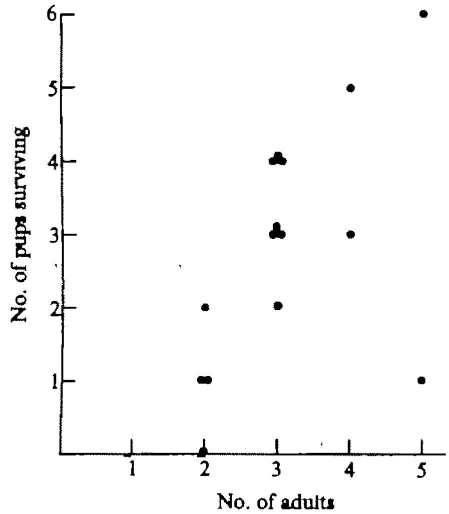

Fig. 1 Number of adults per family and pup survivorship. $n = 15$; Spearman rank correlation coefficient, $R_s = 0.967$; $P < 0.01$.

to prey on young pups, but can be successfully driven away by one adult jackal. Families with more adults (that is, those with helpers) had an attendant adult at the den a higher proportion of the time, thus providing greater protection for the pups. Helpers also play, groom, and help teach the pups to hunt. Quantitative details of helper contributions will be published elsewhere.

Pups first emerge from the den at approximately 3 weeks of age and are weaned at 8–9 weeks. By 14 weeks they are well coordinated, no longer use a den, and are starting to forage with adults. All observed mortality has occurred within this initial 14-week period. This is the time within which the pups are most vulnerable to food deprivation and predation, and the time period in which major contributions are made by helpers and parents.

The presence of helpers correlates positively with pup survivorship and was significant to the 0.01 level (Fig. 1). On average, each helper added 1.5 surviving pups to the litter. One aberrant group (litter number 15) had three helpers initially and only one surviving pup. This is the only family in which a helper has been observed to remain for more than one year, and the parents were old. At 14 weeks of age, only one pup remained, and was cared for almost exclusively by the second year female helper. The other two helpers had disappeared. Thus this family had old parents, and for part of the critical period for pups, only one helper.

The presence of helpers seems to be independent of food density. In the study area, jackal territories in the core and periphery of the woodland vegetation differ in the density of an important prey species, the grass rat (*Arvicanthus niloticus*). In a core territory (VIII), trap–recapture data on *Arvicanthus* density varied from 7,792 (November 1976) to 32,083 rats km^{-2} (July 1977). In a peripheral territory (VII), *Arvicanthus* varied from 3,125 (November 1976) to 13,125 (July 1977) (R. Senzota, personal communication). The ratio of rat density between core and peripheral territories was 2.5:1. However, this difference in food availability did not seem to affect the presence of helpers and pup survivorship. In territory VIII, a core territory with high prey density, the resident pair with one helper had four pups survive from the 1976 litter. None of these pups stayed as helpers. In June 1977, the same pair had a litter of five pups, and none of them survived. By contrast, in 1976, in peripheral territory VII, the resident pair with no helper had a litter of five pups and one survived. This pup remained with his parents. In July 1977, the same pair had a litter of six pups and one helper. Three pups survived. Even in the peripheral area with the lower *Arvicanthus* density, there is still a large biomass available at whelping time ($13,125 \times 60$ g = approximately 800 kg km^{-2}). Thus even in the peripheral area there is probably an adequate food supply and the critical factor in pup survival is the number of provisioning adults that can capture that prey and make it available to the pups.

Hamilton's theory of inclusive fitness seems particularly relevant to the observed behaviour of helpers[5]. Inclusive fitness consists of: (1) the individual's personal fitness in terms of reproductive success; and (2) the effects of his behaviour on the reproductive fitness of his conspecifics multiplied by their degree of relatedness. 'Inclusive fitness', therefore, examines the lifetime effect of an individual's behaviour on the next generation's gene pool, not only in terms of his own reproduction but also that of related individuals[6]. According to Hamilton an individual's behaviour will be favoured by natural selection if it increases inclusive fitness.

Jackal helpers are as closely related to their full siblings as they would be to their own offspring. As their contributions as helpers increase pup survivorship, their own inclusive fitness is enhanced by kin selection until such time that breeding is attempted. In fact, an adult helper gains more (yield 1 pup per adult) by being a helper of its parents than by finding a mate and raising its own pups aided only by its mate (yield 1/2 pup per adult). Helpers may also derive benefits from extended experience on the home territory in terms of increased survivorship, increased long-term reproductive success and acquisition of a portion of the home territory[7]. Parents benefit from the presence of helpers from increased reproductive success due to higher pup survivorship, and increased inclusive fitness as parents accrue more reproductive benefits by helpers investing in their pups ($r = 1/2$) than by helpers producing their own pups (grandpups $r = 1/4$). Thus, it is in the parent's best interest to retain helpers. The benefits of retaining helpers are potentially limited by available food resources.

I thank James R. Malcolm, R. Senzota, Inayet Anjari and the staff of Ndutu Tented Camp for their assistance, T. Moermond, G. Stephenson, L. H. Frame and G. Frame for reading the manuscript, and the Tanzanian Scientific Council, Tanzanian National Parks, the Ngorongoro Conservation Area Authority and the Serengeti Research Institute for making this research possible. Is intragenic recombination a factor in the maintenance of genetic variation in natural populations?

INTRAGENIC recombination between two different existing alleles in a population can create new alleles. The role of this process in maintaining variation in a natural population has been investigated[1] by assuming that a gene consists of two sites, each of which can mutate to an infinite number of unique 'alleles' (the infinite allele model of Kimura and Crow[2]). Using this model it was shown that if the product of the population size, N, and the mutation rate, μ, is $\gg 1$, and the recombination rate, r, is the same order of magnitude as the mutation rate, then intragenic recombination significantly increases the number of alleles maintained in a finite population. Moreover, this is not equivalent to an increase in the mutation rate as the variance of homozygosity and the variance of the number of alleles are larger. This implies that the sampling theory of neutral alleles developed by Ewens[3] does not apply to the situation where intragenic recombination is important in maintaining variation[4]. Application of these results to the study of intragenic recombination in natural populations would require a large number of independent samples in order to estimate the variance of homozygosity and the variance of the number of alleles. However, data from natural populations usually consist of the number of alleles and their frequencies in a single sample. Therefore, for the effect of intragenic recombination to be observable, there must be a detectable change in the distribution of the allele frequencies in a sample which contains k alleles. We present here the results of Monte Carlo simulation which show that intragenic recombination in the equilibrium population increases the frequency of the most common allele, increases the number of alleles which occur only once in the sample, and increases the homozygosity.

The Monte Carlo simulation utilises the same algorithm we used previously[1]. Briefly, for each of the $2N$ genes of the next generation two genes are selected at random with replacement from the present generation; one of the four alleles, the two recombinants and the two non-recombinants, are then selected with probabilities $r/2$, $r/2$, $(1-r)/2$ and $(1-r)/2$, respectively; and lastly, it is determined whether a mutation occurs at each of the two sites with probability ν where $\mu = 2\nu$. This is equivalent to the model of random drift with two loci[5]. For the simulation of intragenic recombination, the parameter values, $2N = 200$, $4N\mu = 4$, and $r = 10\mu$, were used because it has been shown that there is a significant effect of recombination on the allelic variation maintained in a population with these parameter values[1]. A sufficient number of samples, each with k alleles, is obtained in the following manner: each sample is the first generation which contains k alleles and which occurs at least $2N$ generations after the previous sample. Samples are collected at least $2N$ generations apart to minimise the effects of co-variance among samples. The results presented are for 400 samples with $k = 25$ and are representative of those obtained for other values of k. For comparison, 400 samples with $k = 25$ alleles are collected in the same manner with the parameter values, $2N = 200$, $4N\mu = 8$, and $r = 0$. $4N\mu = 8$ is a valid choice of the parameter value for the case of no recombination, as Ewens[3] has shown that the distribution of allele frequencies conditional on k is independent of the value of $N\mu$. The parameter value, $4N\mu = 4$, is not used because the probability that a generation contains 25 alleles is very small.

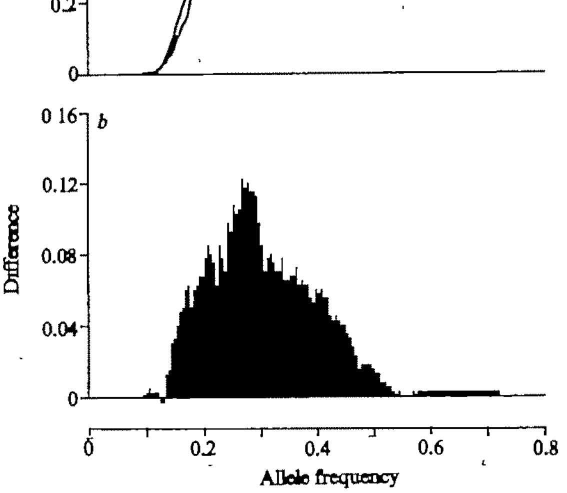

Fig. 1 Cumulative distributions of the frequency of the most common allele from Monte Carlo simulation of intragenic recombination between two sites. For each set of experiments 400 samples were collected, each sample with $k = 25$ alleles, at least $2N = 200$ generations apart. In the case of intragenic recombination, $4N\mu = 4$ and $r = 10\mu$; in the case of no recombination, $4N\mu = 8$. *a*, Cumulative distributions of the frequency of the most common allele; *b*, difference between the cumulative distributions.

Table 1 Statistics of the allelic distributions of 400 samples from Monte Carlo simulation of intragenic recombination

	$r = 0$		$r = 10\mu$	
	Mean	Variance	Mean	Variance
Frequency of the most common allele	0.234	0.00532	0.258	0.00841
Number of singleton alleles	7.255	4.85	7.78	5.63
Homozygosity	0.119	0.00132	0.134	0.00264

$2N = 200$ and $k = 25$.

Three variables are used to compare the allelic distributions of the two sets of samples: the frequency of the most common allele, the number of alleles which occur only once in the sample, and the homozygosity. The cumulative distribution of the most common allele in each of the two sets of samples is shown in Fig. 1, and also the difference between the two distributions. It is seen that the frequency of the most common allele is greater in the case of intragenic recombination than that without recombination. As shown in Table 1, this difference holds for the means and variances of the frequency of the most common allele, the number of alleles which occur only once, and the homozygosity.

Is this pattern of differences observable in data from natural populations? We have stated previously[1] that the observed intragenic recombination rate at the *rosy* locus in *Drosophila*[6] (which varies from 1.2×10^{-4} to 7.2×10^{-6}) and the observed number of alleles in samples from natural populations[7,8] are such that intragenic recombination could have a significant role in the maintenance of variation at this locus. The data of Coyne[7] and Singh, Lewontin and Felton[8] have recently been extensively re-analysed by Waterson[9] and it was found that the frequency of the most common allele is significantly too large in each of the pooled samples. There was also significantly greater homozygosity and the singleton alleles were too frequent. The results of the simulation of intragenic recombination presented here are in the same direction as that observed in these data from natural populations. Therefore, intragenic recombination may be responsible for some of the excess of rare and of common alleles observed in samples from natural populations.

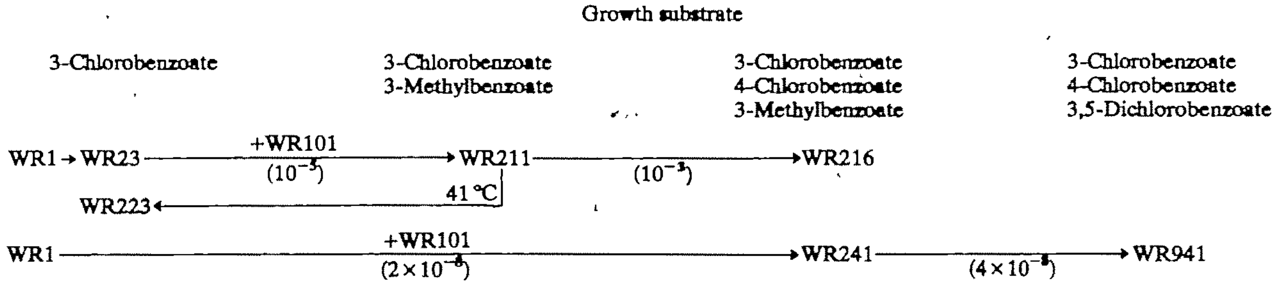
Construction of haloaromatics utilising bacteria

LARGE amounts of novel organic compounds are released into the environment by the rapidly growing chemical industry. The main agents for returning natural and, presumably, synthetic organic compounds to the carbon cycle are bacteria and fungi, provided that catabolic enzymes with appropriate specificities, transport systems and regulatory mechanisms can be activated. One or several of these conditions for total degradation do not seem to be fulfilled for certain types of man-made compounds, in particular, the halogenated aromatic hydrocarbons. In this report, we demonstrate the transfer of the TOL plasmid from *Pseudomonas putida* mt-2 (WR 101) to *Pseudomonas* sp. B13 (WR 1) enabling novel strains to be isolated which can utilise various chlorosubstituted benzoates as their sole source of carbon and energy.

Pseudomonas sp. B13 (WR1) is one of the few bacteria known to be able to use haloaromatics such as 3-chlorobenzoate or 4-chlorophenol as the sole source of carbon and energy[1,2]. Comparative kinetic studies on the 1,2-dioxygenation of benzoate[3], dehydrogenation of dihydrodihydroxybenzoates[4] and 1,2-dioxygenation of catechols[5] indicated that the stereospecificity of the initial enzyme hinders the utilisation of the 2- and 4-chlorobenzoates in addition to 3-chlorobenzoate in this strain. We did, however, demonstrate that the TOL plasmid coded[6,7] benzoate 1,2-dioxygenase in *Ps. putida* mt-2 ((WR101) is considerably less specific and readily co-oxidises chlorosubstituted benzoates, including 4-chlorobenzoate[3]. Nevertheless in contrast to *Ps.* sp. B13, this organism cannot totally degrade halocatechols. Substrate utilisation did not occur, but a number of halosubstituted metabolites of the meta cleavage pathway were accumulated, together with unstoichiometric amounts of chloride (our unpublished work).

Table 1 Construction of halobenzoate-utilising strains



Donor and recipient cultures were grown for 24 h on nutrient agar plates. The bacteria were suspended in phosphate buffer *p*H 7.4, 50 mM to 3×10^8 cells ml^{-1}. Portions of each culture were mixed so that the ratio of donor and recipient was 2 · 1. One ml of the resultant mixture was filtered through 0.2 µm Millipore filter. The filter, after being placed on the surface of nutrient broth agar plates, was incubated for 12 h at 28 °C and then vigorously whirlmixed with 4 ml phosphate buffer to resuspend the cells. The resulting suspension was plated on the appropriate selective medium. The frequency of transfer given in parentheses are defined as the number of exconjugants per donor cell or spontaneous mutation frequency on the selective substrate.

Exconjugants like WR 241, which is able to grow on 4-chlorobenzoate (see Table 1) were obtained by the Millipore filter technique after selection on 4-chlorobenzoate agar plates. Differentiation by nutritional pattern (Table 2) and analysis of catabolic enzymes (to be published elsewhere) clearly indicated that WR 241 originates from WR 1 as the recipient strain. The ability to utilise 4-chlorobenzoate is the only new property in strain WR 241. Other exconjugants, not listed here, were isolated which could utilise *p*-toluate in addition to 4-chlorobenzoate. From this, it can be deduced that WR 101 functioned as the donor strain. By mating WR 101 with the streptomycin-resistant strain WR 23 of WR 1 and selection on *p*-toluate–streptomycin agar plates, strains of type WR 211 were found which could use both growth substrates of the parent strains, namely, 3-chlorobenzoate and *p*-toluate. By plating WR 211 on 4-chlorobenzoate, spontaneous mutants like WR 216 were isolated which could grow on the new substrate.

Exconjugants, such as WR 241, appeared with almost the same frequency as the product of the frequencies which were observed during selection for strains WR 211 and WR 216. Phenotypic expression for the utilisation of 4-chlorobenzoate seems to require a mutation in addition to the transfer of the TOL plasmid. During growth at 41 °C strain WR 211 can be cured, consequently, WR 223, the resulting strain, lost its ability to grow on *p*-toluate.

Biological devices for the adaptation to novel organic chemicals are mutations in structural genes leading to the evolution of enzymes with novel specificities and activities[8-11] and mutations changing regulatory controls[12,13]. In another study, the detectable response to stress by novel organic molecules was the hyperproduction of pre-existing enzymes due to gene duplication[14]. The active sites of these enzymes possess a slight affinity for compounds of related chemical structure. The second copy enables mutations to accumulate, which are not immediately constrained by selection. An ideal mechanism for accelerated enzymatic adaption to novel substrates is suggested by the observation that the genes for catabolic enzymes are carried on extrachromosomal elements[15,16].

In the present study, *Ps.* sp. B13 acquired the ability to utilise novel substrates like 4-chloro- and 3,5-dichlorobenzoate by conjugation with *Ps. putida* mt-2. The initial turnover of the halogenated benzoates was provided by the TOL plasmid-coded enzymes, whereas total degradation and utilisation was accomplished by the halocatechol-degrading enzymes of the recipient strain. In addition, exconjugants were observed in which *Ps. putida* mt-2 seemed to have acquired the genes coding for the enzymes of halocatechol catabolism (our unpublished work). In general, the acquisition of the genes of halocatechol catabolism could overcome accumulation of toxic halocatechols which frequently occurs during co-metabolism of haloaromatics in arene or methylarene-utilising bacteria. We found the same enzymes for total degradation of halocatechols in other pseudomonads which are capable of utilising a variety of haloaromatic compounds. These had been isolated from continuous adaptation cultures in the presence of *Ps.* sp. B13. The combination of methylarene-utilising strains providing high co-metabolic activities for halosubstituted analogues by their initial enzymes, together with the halocatechol-degrading enzymes of *Ps.* sp. B13, could be a general concept for the construction of new strains (see Fig. 1) which could degrade halosubstituted benzenes, phenols, anilines and naphthalenes, totally.

Selection of predation-resistant bacteria in continuous culture

VARIOUS models of predator–prey interactions predict the occurrence of reciprocal oscillations in the densities of the predator and its prey[1]. Some models predict undamped, neutrally stable oscillations (the Lotka–Volterra model), whereas others predict damped oscillations, the two populations gradually approaching an equilibrium. Few attempts have been made to test these models, possibly because of the rarity of suitable experimental systems. The predatory bacterium *Bdellovibrio*, which preys on other bacteria, provides an ideal system in which predator–prey interactions can be studied in a convenient and accurate way. As part of a study of the ecology of *Bdellovibrio*[2] we have inoculated bdellovibrios into a continuous culture of prey bacteria growing in a chemostat. The introduction of the bdellovibrios was followed by reciprocal population oscillations.

0028-0836/79/0277—0386$01.00

Table 1 Comparison of *Photobacterium leiognathi* E28 (original strain, O) and two strains (A, B) isolated from the chemostat after 6 days of mixed cultivation with *Bdellovibrio*

	O	A	B
Cell morphology	Rod (pairs)	Rod (pairs)	Oval (in chains)
Colony morphology*	Translucent	Translucent	Opaque
Doubling time in batch culture*	22 min	23 min	36 min
Maxima light intensity (quanta s^{-1} ml^{-1}) in batch culture*	6.0×10^{11}	8.8×10^{11}	1.8×10^{9}
Bdellovibrio plating efficiency†	1.0	1.0	$<1.0\times10^{-7}$‡
$t_{1/2}$ (time to reduce prey population to half original size after mixing with *Bdellovibrio* at a ratio of 1:10)	10.3 min	10.3 min	>60 min

* On medium MPY (ref. 3).

† Determined as described by Marbach *et al.*[3].

‡ Macroplaque was obtained when 10^7 or more *Bdellovibrio* plaque-forming units were placed on the lawn.

However, the oscillations did not persist and were not damped. Instead, a new system evolved in which a bdellovibrio-resistant mutant was detected.

The bacterium which served as prey was the luminescent *Photobacterium leiognathi* E28 (ref. 2). It was grown in a chemostat set to hold a carrying capacity of 10^8 cells ml^{-1}. After the culture reached a steady state, a small inoculum of the predator, marine *Bdellovibrio* BM4 (ref. 3), was introduced. Figure 1 depicts the pattern of growth which followed: classical oscillations are apparent up to the sixth day (in this specific experiment); the pattern then changes, as the prey population which was initially homogenous, begins to show morphologically different types of colonies. From this point the prey population consisted of two different genetic types—one resembling the wild type, having a strong bioluminescence (type A), the other being more opaque, and dark (type B). Single colonies of both types were streaked on agar and isolated into axenic cultures. Figure 2 shows the growth curve and the bioluminescence of the two types isolated from the chemostat, in comparison with the strain with which the chemostat was originally inoculated. Type A grows at a similar growth rate and emits light of a similar intensity to that of the original strain; type B grows at a slower rate and emits light at an intensity less than 1% that of the original strain.

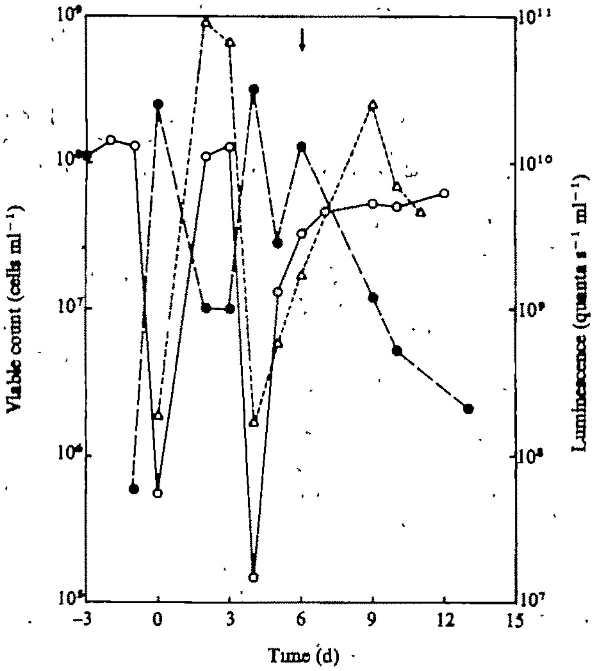

Fig. 1 Growth of *Bdellovibrio* BM4 and *Photobacterium leiognathi* E28 (both strains streptomycin-resistant) in a mixed culture in a chemostat at a dilution rate of 0.1 h^{-1}. The medium used was MPY (ref. 3) diluted 1:15 and supplemented with streptomycin (100 μg ml^{-1}) to reduce the possibility of chance contamination with bacteria. The prey (○) was allowed to reach a steady state, then the flow was stopped and bdellovibrios (●) were inoculated and allowed to grow for 24 h in batch culture. At time zero the flow was turned on again and kept constant throughout the experiment. The triangles indicate the light intensity of the culture, measured by a photometer similar to the one described by Mitchell and Hastings[7]. The arrow indicates the first appearance of mutant colonies on the plates. Viable counts were done as described by Marbach *et al.*[3], using plates supplemented with streptomycin.

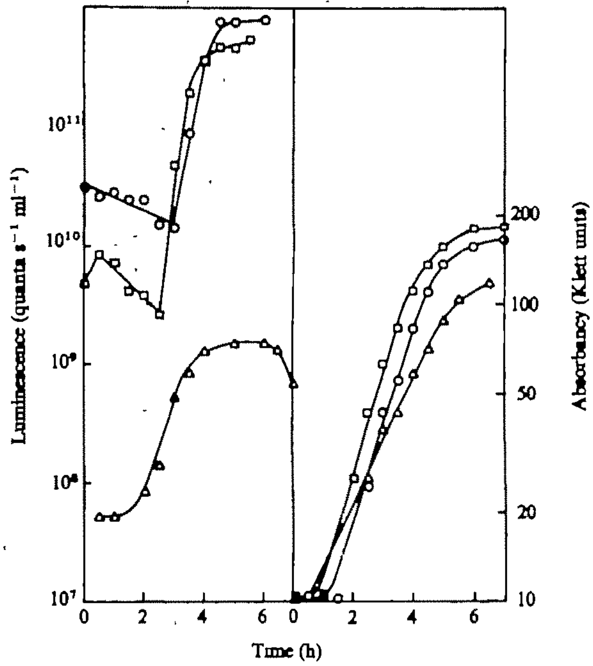

Fig. 2 Growth curve and bioluminescence of *Photobacterium leiognathi* E28 and of the two colony types isolated from the chemostat. □, The original strain inoculated into the chemostat; ○ type A; △, type B. All three cultures were grown in MPY medium in a shaking water bath at 26 °C. Absorbance was measured in a Klett–Summerson photometer using filter no. 42.

When a suspension of each of the two types was mixed with the bdellovibrios (at a ratio of 10 bdellovibrios per prey bacterium), type A cells were immediately attacked and penetrated, as observed under the phase-contrast microscope, while type B cells remained untouched by the bdellovibrios. Death of the type A photobacteria followed the attack by the bdellovibrios (Table 1).

Plaque assay gave a similar picture: the efficiency of plating of the same bdellovibrio suspension on lawns of type B was at least 10^7 times lower than on type A or on the original strain (Table 1).

In summary, a two-membered culture of a *Bdellovibrio* and a fast-growing susceptible prey evolved into a three-membered culture containing bdellovibrios, a prey type similar to the original, and a dark mutant, which grows more slowly and is resistant to the bdellovibrios. The different growth rates of the luminous bacterium and its dark mutant would exclude the possibility of their coexistence in the chemostat unless there is an interaction between the two strains. Indeed, when the two were inoculated together in a chemostat operating in the same conditions as the three-membered culture, but without the bdellovibrios, type A was maintained in a steady state, while type B was washed out. The resistance of the dark mutant to the bdellovibrios would not allow the latter to reproduce so the coexistence of predator and mutant is also unlikely. However, a mutant with slower growth rate and greater predation resistance may be able to coexist with the wild type and its predator in a stable three-membered system. The stability of such a system has been theoretically predicted by Cramer and May[4] who, using simple three-species mathematical models, showed that a two prey–one predator system could be stable in circumstances where the two-prey system would in the absence of predation be unstable due to competition.

The possibility of coexistence of a predator and its prey in a homogenous environment has also been questioned[5]. Van den Ende[6] studying the interaction of a protozoan predator (*Tetrahymena pyriformis*) and its bacterial prey (*Klebsiella aerogenes*) in continuous culture concluded that the coexistence of the two organisms was due to spatial heterogeneity created in the system by the prey bacteria. No such heterogeneity could be observed with the photobacteria, which were homogenously dispersed in the growth vessel; their persistence could be explained by the presence of the slow growing and predation-resistant mutant.

Although *Bdellovibrio* has been known and studied for 16 years, this is the first report of the isolation of bdellovibrio-resistant mutants. Apparently, conditions prevailing in batch cultures do not allow the evolution of such mutants, while growth in a chemostat in the conditions used in this study repeatedly resulted in their appearance.

Unusual maternal–fetal blood glucose concentrations in Weddell seal

FETAL whole blood glucose levels are usually lower than, and fluctuate with, maternal levels. That is, a favourable concentration gradient is maintained to allow for the facilitated transfer of glucose across the placenta from mother to fetus[1,2]. This situation is apparently reversed in the Weddell seal. The concentration of glucose in maternal whole blood is lower than that in fetal blood during at least three metabolic states: in the resting–fasting state, in simulated diving, and in recovery from diving[3]. We report here that one factor contributing to this unusual relationship between maternal and fetal blood glucose is the relatively low gradient between normal blood levels in fetus and mother. This is made possible by high haematocrit values and a low turnover of glucose in both parent and fetus.

Five pregnant Weddell seals (*Leptonychotes weddelli*) weighing 450–500 kg were captured on the fast ice near Ross Island, Antarctica and taken to the Eklund Biological Laboratory at McMurdo Station. Intermittent blood samples were obtained from indwelling maternal and fetal catheters implanted as previously described[4]. Samples of blood (2 ml) were added directly to perchloric acid and treated as before[4]. Glucose levels in neutralised perchloric acid extracts were determined using the hexokinase assay[5]. In several fetal and maternal extracts, glucose was determined also by the glucose oxidase method, the Benedict assay system and by an automated glucose analyser with a linear response over the range 5–50 μmol ml^{-1}. All three assay procedures yielded the same fetal–maternal differences and the same absolute glucose concentrations. To exclude the possibility of the presence of an unusual sugar, whole blood extracts were analysed by gas–liquid chromatography[6]. Glucose was the only major sugar present in maternal and fetal blood; fructose, galactose, mannose, and ribose did not occur in measurable concentrations. The possibility of a significant amount of fructose was also excluded by enzymatic tests using fructose kinase and hexose isomerase to convert fructose to glucose-6-phosphate and then assaying the latter with glucose-6-phosphate dehydrogenase. Establishing the absence of fructose was considered important because of its reported occurrence in cetaceans[7]. Insulin was measured by radioimmunoassay with porcine insulin serving both as the antigen in the preparation of antibodies and as the standard[8].

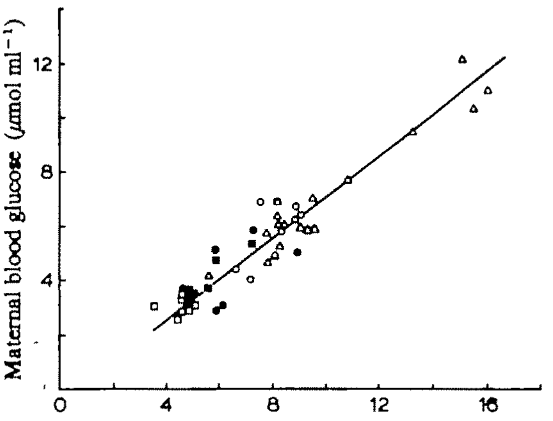

Fig. 1 A plot of glucose concentrations in whole blood of five maternal-fetal pairs. The different symbols refer to different pairs. Blood samples were taken before, during and after simulated diving. The highest glucose values were obtained after intravenous infusion of glucose.

Under resting and fasted conditions (in captivity for at least 12 h), maternal whole blood glucose concentrations ranged between 4 and 6 μmol ml^{-1} compared to 5–8 μmol ml^{-1} in fetal whole blood. Similar levels were found in samples drawn from undisturbed seals asleep on ice. Although the fetal concentrations were consistently higher than maternal ones, the two values tended to fluctuate in unison (Fig. 1).

To better understand how maternal and fetal blood glucose levels are regulated, a glucose load (1.5 g per kg of estimated maternal body weight) was infused over a period of 20 min into

Table 1 Fractional distribution of glucose between plasma and red blood cells in the maternal and fetal Weddell seal compared with the sheep

Species	Condition	Glucose (μmol ml^{-1}) Whole blood	Plasma	Red cells	Ratio plasma: red cells
Weddel seal (adult)	Pre-infusion	3.1	7	0.5	14
	60 min postinfusion	13 5	30	2.5	12
Weddell seal (fetus)	Pre-infusion	3.5	6	2.4	2.5
	60 min post-infusion	15.8	22.5	12.9	1.7
Sheep (adult)	Post-prandial		2.5	0.3	8.3
Sheep (fetus)			0.7	0.2	3.5

the maternal circulation of three pregnant seals. In all three animals, the maternal concentration of glucose in both whole blood and plasma rose to values that exceeded those in the fetus throughout the infusion and for a short period after it was completed, but within 20–40 min fetal blood glucose levels were again higher than in the mother (Fig. 2*a*, *b*). The plasma concentration of insulin increased sharply in both mother and fetus ~15 min after the rise in glucose levels (Fig. 2*b*). In the fetus, the concentrations of plasma glucose and insulin followed similar patterns but in the mother, insulin levels remained elevated for at least 5 h after glucose infusion although glucose concentrations were falling.

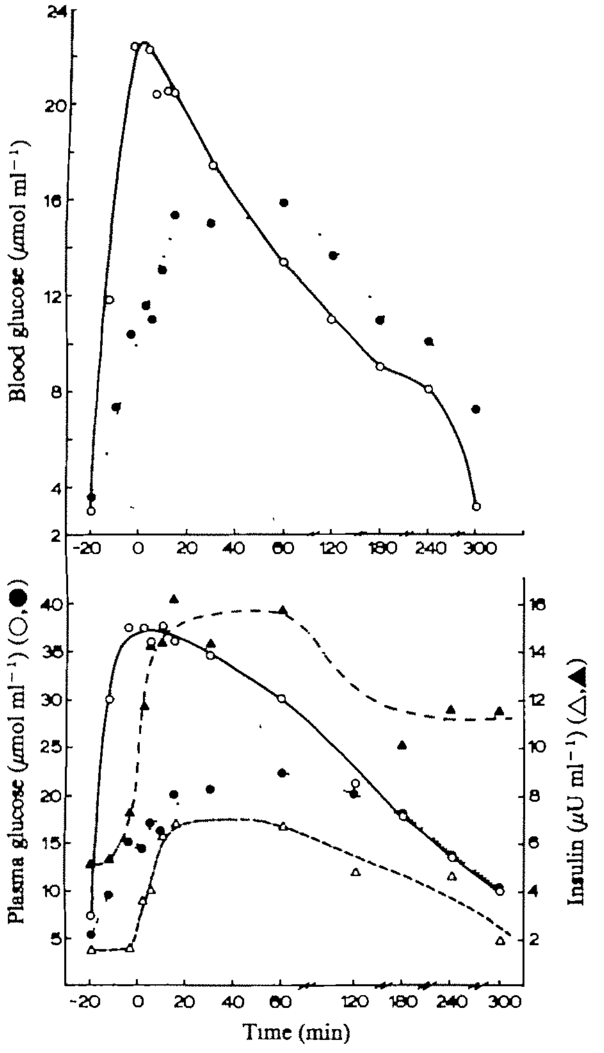

Fig. 2 *a*, Maternal (O) and fetal (●) concentrations of glucose in whole blood following intravenous infusion of glucose 1.5 g per kg. Time zero indicates the end of the 20 min period of infusion. *b*, Maternal glucose (O) and insulin (▲) and fetal glucose (●) and insulin (△) concentrations in plasma from the same glucose tolerance test as shown in (*a*).

As in other mammals, glucose levels are higher in maternal plasma than in fetal plasma and glucose moves from maternal to fetal blood down a concentration gradient. The unusually high glucose content of fetal whole blood relative to the mother arises from several factors. First, the gradient across the placenta is small (~2 μmol ml^{-1}) despite the use of arterial samples which would tend to exaggerate the apparent gradient. This is particularly so after glucose infusion when the gradient disappeared for 2 h (Fig. 2*b*). Second, the ratio of glucose concentrations in red cells to those in plasma in the mother is unusually low whereas that of the fetus is similar to other species (Table 1). Finally, the haematocrit of both mother and fetus is high (~60% and 70% respectively) which has the effect of increasing the ratio of plasma: whole blood concentration of glucose, especially in the mother.

Whereas a high haematocrit increases the O_2 carrying capacity of the blood, it clearly reduces the glucose carrying capacity although to a lesser degree in the fetus because of the greater entry of glucose into fetal red cells. The sustained hyperglycaemia after glucose loading (Fig. 2*b*) suggests that the rate of glucose turnover in the adult seal is low. Likewise, the small gradient of plasma glucose concentrations across the placenta suggests a low turnover rate in the fetus. Thus, neither mother nor fetus is likely to be disadvantaged by having a relatively low carrying capacity for glucose in the blood.

Immunisation against gametes and asexual erythrocytic stages of a rodent malaria parasite

INVESTIGATIONS into the feasibility of vaccinating against malaria have centred mainly on the use of the sporozoite[1,2] or the asexual blood stages[3–6]. Immunisation using sexual stages of malaria parasites has been demonstrated with *Plasmodium gallinaceum* in chickens[7,8]. Gamete vaccines have been used to produce an effective immunity against transmission of the avian malaria parasite, with little or no effect on its asexual erythrocytic stages. More recently, this study has been extended to *P. knowlesi* infections in rhesus monkeys[9]; transmission-blocking immunity and resistance to asexual infection were obtained, but were fully effective only when the vaccine was combined with Freund's complete adjuvant. We report here successful immunisation of mice against the sexual stages of *P. yoelii* using formalin-fixed gametes. In addition to very effective transmission-blocking immunity, the vaccinated mice were strongly protected against asexual erythrocytic stages of the parasite.

Eight-week-old female outbred Theiler's Original (TO) mice were used as vertebrate hosts. The parasite, *P. yoelii nigeriensis*, was cryopreserved (stabilate reference LUMP 1316) soon after cyclical transmission through the vector *Anopheles stephensi*. Parasites from the first passage from the vector were used for initiating an infection.

0028–0836/79/0277—0389$01 00

P. yoelii preferentially invades reticulocytes. Mice were made anaemic with three subcutaneous injections of phenylhydrazine and infected intravenously (i.v.) with parasitised red cells. As a result of the induced reticulocytosis, the parasitaemia rose to 70–80% with 0.5–1.5% of gametocytes. Mice were bled by cardiac puncture into 50 volumes of a suspended animation (SA) solution (0.21% Tris, 0.96% NaCl and 0.2% glucose, adjusted to pH 7.4) in which gametogenesis was reversibly suppressed[10]. The suspension was centrifuged at 500g for 10 min and the red cells were resuspended in a gamete-releasing medium[8] (2.5 vol of 5% NaCl, 2.5 vol of 10% glucose, 20 vol of 1.46% $NaHCO_3$ and 100 vol of inactivated fetal calf serum, adjusted to pH 8.0) in a proportion of 1:3 v/v, and the pH readjusted to 8.0. After 30 min at room temperature gametogenesis was complete and the suspension was centrifuged at 500g for 10 min. This procedure was repeated four times, resuspending the packed material in SA solution, so as to recover as many free gametes as possible. The pooled supernatants were centrifuged at 18,000g for 20 min and the pellet containing gametes was suspended in a solution of 1.0% formalin for 30 min at room temperature. The gametes were washed three times in SA solution at 18,000g. After the final wash, counts were made on a haemocytometer using a phase contrast microscope, and adjusted such that 0.2 ml contained 2×10^7 male gametes.

Table 1 Oocyst production in mosquitoes fed on vaccinated and unvaccinated mice

Day	Unvaccinated mice No. of oocysts per 10 mosquitoes Expt 1	 2	 3	 Mean no. of oocysts per mosquito	Vaccinated mice No. of oocysts per 10 mosquitoes Expts 1, 2 and 3
1	0	0	0	0	0
2	114	1,638	2,162	130.4	0
3	496	498	1,287	76.0	0
4	1,406	40	0	48.2	0
5	0	62	0	2.0	0
Total counts	2,016	2,238	3,449		

In each experiment, 3 vaccinated and 3 unvaccinated mice were given a blood-induced challenge infection. Batches of mosquitoes were fed on each group of mice on days 1–6 of the infection. The mosquitoes were maintained at 24 °C and oocyst counts were done 1 week later.

The vaccine contained, in addition to male and female gametes, asexual parasites which under the light microscope appeared to be free of their host red cells, and occasional red cell 'ghosts' and white cells. 0.2 ml of the vaccine contained 2×10^7 male gametes, $6–8 \times 10^6$ female gametes and $10^5–10^6$ asexual parasites. 2×10^7 male gametes were obtained from 5.0 ml of infected blood. Each mouse received three doses of the freshly prepared vaccine i.v. at weekly intervals, that is, a total dose of 6×10^7 male gametes. One week after the final dose of the vaccine, vaccinated mice and an equal number of age-matched control mice were inoculated i.v. with 2×10^5 parasitised red cells. Thin blood films were made daily, stained with Giemsa and the parasitaemia and gametocytaemia ascertained. On days 1–6 after challenge, mosquitoes were fed on vaccinated and control mice, one cage per group. Any unfed female mosquitoes were removed from the cages and 1 week after feeding, 10 mosquitoes from each cage were dissected and the midguts examined microscopically for oocysts.

Results were obtained from three separate experiments involving nine vaccinated and an equal number of control animals. The infection was fatal in all but one of the control mice. Death of the control mice occurred either on days 6 and 7, with parasitaemias of 20–30% (Fig. 1*a*) or on days 18 and 19, with peak parasitaemias of 50–60%. In contrast, the vaccinated mice were apparently aparasitaemic by day 12, with an average clearance time of 8.8 d. The highest parasitaemia recorded in the vaccinated mice was 3.1%, reached on day 4 (Fig. 1*a*). The average gametocyte counts are represented in Fig. 1*b*. Mosquitoes fed on control mice had high total oocyst counts, these being derived mainly from feeds taken 2, 3 or 4 d after challenge. Mosquitoes fed on vaccinated mice showed no oocysts at all in their midguts throughout the infection (Table 1).

These experiments demonstrate a very effective immunity which blocks transmission. It does not require the use of an adjuvant and we are now investigating whether fewer gametes and/or smaller numbers of immunising doses can be used; preliminary studies indicate that a single dose can be equally effective. Immunity to asexual erythrocytic stages, though not complete, was also pronounced, manifested by a significant lowering of parasitaemia and a 100% survival as compared to the control mice, in which the parasitaemia was higher and the infection fatal in almost all of the mice. Gwadz and Green[9] used a gamete/trophozoite antigen mixture in their experiments with *P. knowlesi* and this also induced immunity against asexual parasites. There are two possible explanations. First, contamination of the gamete vaccines with asexual stages might be responsible. Experiments by Playfair *et al.*[6] and our own experience (unpublished) with saponin-lysed, formalin-fixed asexual stage parasites used as a vaccine without an adjuvant, have resulted in an effective immunity to blood-induced *P. yoelii* infections. The alternative proposition would be that gametes protect against asexual stages because they have protective antigens in common.

It is encouraging that such an effective block on transmission is possible by vaccinating with a relative crude antigen preparation, and without the need for an adjuvant. Further improvements both in methods of vaccine preparation and in its presentation are possible.

Changes in ocular dominance induced in monocularly deprived lambs by stimulation with rotating gratings

AMBLYOPIA in children aged about 6 yr can be rapidly diminished by stimulating the amblyopic eye alone with rotating disks of square-wave gratings[1]. Such exposure for four periods each of 7 min has brought many of the patients up to 6/6 acuity, in some cases, after 'patching' of the good eye had been largely ineffective. However, in children of this age, the 'critical period' has probably passed. We decided to study the effects of presenting rotating gratings during the critical period, when the visual system is known to be acutely sensitive to visual deprivation. Could changes in the ocular dominance of cortical neurones be induced even in the relatively unfavourable conditions of moderate to light anaesthesia? We report here that monocular deprivation of 2–3 d in young lambs results in a marked decrease in the number of cells in the primary visual cortex which can be stimulated through the deprived eye, but that this can be rapidly increased by subsequent brief exposure of the deprived eye to a rotating square-wave grating. We chose to work on lambs and a pygmy goat in which one eye had been closed for a few days shortly after birth because we thought that such treatment would leave few cells driven initially by the deprived eye. As the visual cortex at that time is showing its greatest plasticity, it seemed likely that short exposures to the gratings would then have their greatest effect on the ocular dominance. Others had used repeated stimulation by moving bars on single cells of normal animals, but had obtained rather slight and transient effects[2]. We hoped to obtain reasonable changes in eye dominance during the limits of single acute experiments. Seven animals were used. They had normal binocular visual experience until the 4th day of life and were then monocularly deprived for either 2 (nos 1–4) or 3 (no. 5) d, after which they were anaesthetised and used for the experiment.

In the earlier experiments we anaesthetised the lambs and pygmy goats with 2% halothane followed by intravenous (i.v.) pentobarbitone, 10 mg per kg per h, for surgical anaesthesia, and 0.5–3.0 mg per kg per h pentobarbitone during recording. Although we gave the least pentobarbitone necessary during preparation for full anaesthesia, the blood pressure usually began to fall in these animals within 3–4 h and i.v. dextran was only temporarily effective in raising the blood pressure. The animal tranquilliser acetylpromazine (Crookes) was used to reduce the total dose of barbiturate given, but infusion was often necessary to maintain blood pressure. This had no observable effect on cortical responses and it does not cross the blood–brain barrier. In later experiments we used Althesin (Glaxo) 0.1 ml per kg, i.v., repeated as required, for surgical anaesthesia, followed for recording by 0.5–3.0 mg per kg per h pentobarbitone with 60% O_2, 40% N_2 mixture. The blood pressure in these experiments was well maintained without other assistance, and the cortical responses during the earlier hours of recording were much brisker. These difficulties are peculiar to lambs and kids between 3 and 14 d after birth.

To prevent large sampling errors, we avoided penetrations normal to the surface. Penetrations on the medial side of the ectolateral sulcus gave tracks in V1 of up to 3.5 mm long, usually parallel to the cortical surface. On average we sampled from six

Table 1 Summary of ocular dominance distribution in the seven experimental animals

* The difference between the pre- and post-stimulation is significant at $P \leq 0.01$.

ocular dominance columns for each sample of 60–100 cells both before and after stimulation by the gratings. All ocular dominance distributions seen in animals deprived for 2–3 d during the first week of life give very similar patterns (Table 1). Also, collecting 100 cells takes about 5 h, and there is no statistical difference between the distribution of dominance in the first 50 and the last 50 cells collected, so that neither sampling nor the passage of time disturbs the distribution.

Single unit recordings were obtained from the striate cortex contralateral to the deprived eye, for in a normal animal in this hemisphere the experienced eye would chiefly excite only 20% of the cells (ocular dominance groups 5–7, Fig. 2*a*. Tungsten-in-glass microelectrodes with impedances 1–5 M at 1,000 Hz were used[3]. Visual stimuli were hand-held targets moved against a screen 90 cm from the eyes. Unit properties such as orientation specificity (through each eye) and receptive field type were recorded, but we concentrated mainly on ocular dominance, that is, the degree to which a cell could be driven through one eye or the other.

Whether the responses were from visual areas 1 or 2 (V1 or V2) was determined during the experiment from the visuocortical map produced and subsequently verified in histological sections. In these animals the effects of monocular deprivation for 2–3 d are more marked in V1 than in V2, and so we describe only the units in V1. The presence or absence of spontaneously active but undrivable units was also noted.

Except for the control animal (no. 7), the experimental procedure was the same for each of the other four lambs. The deprived eye was opened and a large sample of single units was obtained from V1 during the first few hours. The experienced eye was then closed and the originally deprived eye was stimulated with rotating gratings for periods of 45 to 90 min. Six different spatial frequencies (ranging from $\frac{1}{4}$ cycle deg^{-1} to 8 cycles deg^{-1}, see Fig 1) were presented sequentially in random order during this period, each frequency for about 5 min at a rotation speed of 2 r.p.m.. The whole procedure was then repeated at a faster rotation speed (4–6 r.p.m.). The grating was mounted on a circular disk and subtended at an angle of 35° at the eye. The deprived eye fixated the centre of the grating and was also its axis of rotation. The exact durations of stimulation varied between animals (see Fig. 1 legend).

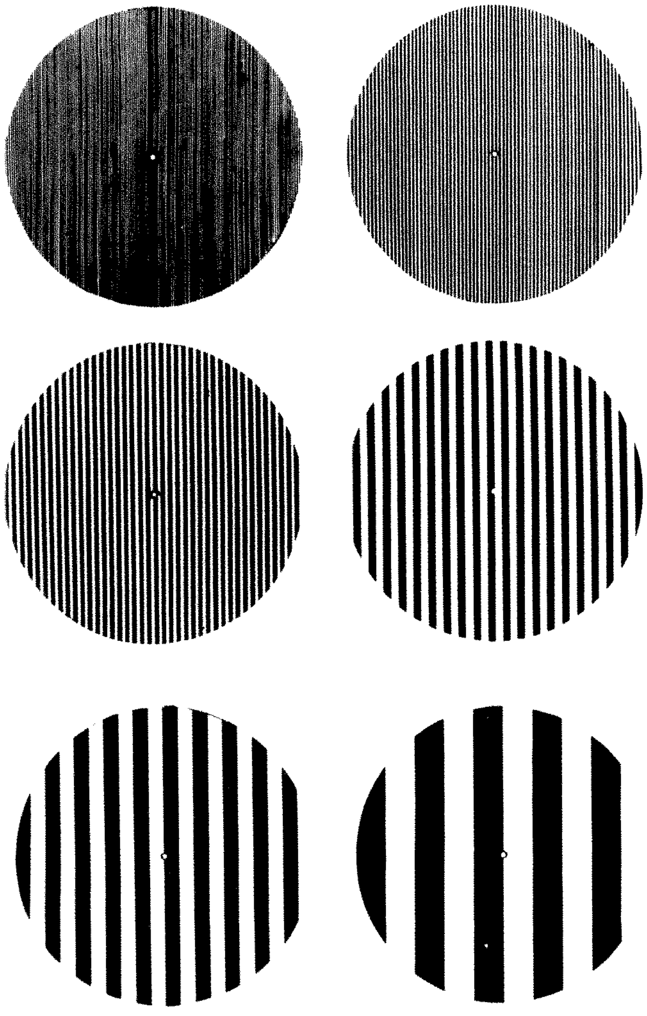

Fig. 1 High-contrast square-wave gratings used in the experiment to stimulate the deprived eye (see text). The spatial frequencies used were 8 cycles deg^{-1} to $\frac{1}{4}$ cycle deg^{-1}.

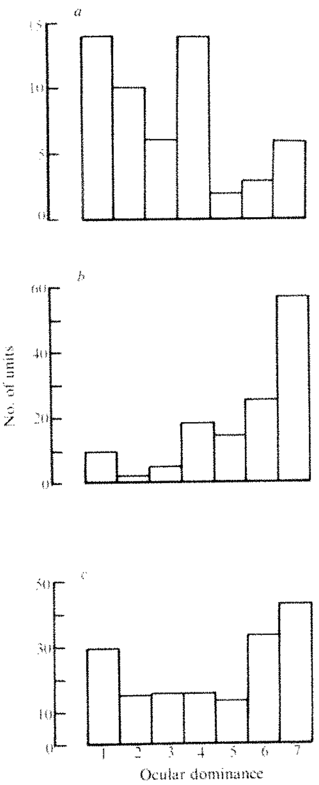

Fig. 2 Ocular dominance histogram of a normal lamb (*a*) and summed histograms of the four monocularly deprived animals used in the grating experiment and mapped within 10 d of birth; before (*b*) and after (*c*) stimulation. The convention of Hubel and Wiesel[7] is followed: group 1, driven only through the contralateral eye; 2, contralateral eye is much more effective than ipsilateral eye; 3, contralateral eye slightly more effective than ipsilateral eye; 4, the cell can be driven equally through either eye; 5, the ipsilateral eye slightly more effective than the contralateral eye; 6, the ipsilateral eye is much more effective; 7, can be driven only through the ipsilateral eye.

After grating presentation to the deprived eye, both eyes were closed for about 45 min to allow 'consolidation', as it has been reported that a short period of binocular deprivation may enhance the effects of selective visual experience[4]. Both eyes were then opened again and a new series of penetrations was made to obtain large samples of units. These data were then used for constructing the post-stimulation ocular dominance histograms. A striking shift in ocular dominance was produced by stimulation with rotating gratings. In the stimulated animals there was an increase in responsiveness of cortical cells to stimulation through the deprived eye, most marked in animal 5. These changes remained stable during the post-stimulation recording period (4–6 h).

Two control experiments were also carried out to determine whether the changes observed were specifically due to the presentation of gratings to the deprived eye. In lamb 7, the surgical procedure used was the same as in the other animals, but instead of presenting a rotating grating, the deprived eye was left open for 1 h (with the experienced eye closed) and was exposed to people walking around in the room. The pre- and post-control ocular dominance histograms in this animal were almost identical. Also, from ocular dominance determinations at the beginning and end of 10 h of repeated visual testing of the two eyes, it is clear that mere passage of time under anaesthesia, even with repeated visual testing, does not produce a reappearance of units dominated by the deprived eye.

Lamb 6 was also used for a control experiment. Our sample of neurones from the other four animals indicated the shift of ocular dominance to be expected from 2 d of monocular deprivation; usually about 6–9% of the total number of neurones were chiefly excited through the deprived eye (ocular dominance groups 1, 2 and 3) as compared with 50% in the normal lamb (Fig. 2*a*). In lamb 6, we opened the deprived eye and closed the experienced eye, and then allowed the animal to walk around the laboratory for 1 h 15 min to allow random visual stimulation of the initially deprived eye before anaesthetising the animal for recording. Several penetrations were then made to obtain a sufficiently large sample of neurones for the ocular dominance distribution.

The was a marked increase in the units driven equally well through either eye (ocular dominance group 4); this requires further investigation. However, the increase in cells dominated by the originally deprived eye was far less than that produced by exposure to the rotating grating for the same period in the other three animals. Hence, random visual stimulation of the deprived eye, even in a conscious animal, may be less effective than a rotating grating. This same animal was then exposed to a rotating grating with only the deprived eye open, and there was a sharp rise in the number of cells driven by the deprived eye.

It is not yet clear whether rotating gratings are the optimal stimuli for producing changes. Experiments on kittens suggest that changes in ocular dominance after reverse suturing begin only after 3 d of visual stimulation[5], and it would be of interest to replicate our experiments using kittens. However, we were not concerned to find the optimal stimulus to reverse the effects of deprivation, but rather, a rapid way of increasing the proportion of cells driven by the deprived eye. Banks *et al.*[1] found that the effect could be produced in children in whom the critical period had probably ended. In two later experiments in monocularly deprived lambs however, the effect could not be obtained after the end of the critical period. Although the revolving grating increases ocular dominance in our animals and improves visual acuity in patients, this does not imply that the stimulation is acting on the same parts of the visual pathway in both cases.

We therefore conclude that ocular dominance can be changed in periods at least as brief as 1 h, even in an anaesthetised preparation. The mechanism underlying this change in ocular dominance is at present obscure. Experiments are in progress to find out whether the effects of stimulating one portion of the visual field of the deprived eye with a grating may spread to adjacent regions within the same field, and not remain confined to the stimulated area alone. This would tell us whether some central diffuse excitatory mechanism is involved. The preparation would also be useful for studying such pharmacological effects as reported by Kasamatsu and Pettigrew[6].

Because of its rapidity of onset and long duration, this effect may provide a neurophysiological approach to understanding the nature of some long-term changes in the central nervous system.

Dexamethasone-induced accumulation of a fibronectin and collagen extracellular matrix in transformed human cells

NUMEROUS differences have been demonstrated between normal and transformed cells in culture. One characteristic finding is the presence of a $2\text{–}2.5 \times 10^5$ molecular weight externally disposed glycoprotein (fibronectin) on normal cells and its absence from cell surface association in transformed cells (see refs 1–3 for reviews). Transformed human cells are known to synthesise and shed fibronectin, although at a much lower rate than comparable normal cells[4,5]. Studies using immunofluorescence or immunoperoxidase methods have demonstrated fibronectin in pericellular structures of fibroblasts and myoblasts in what we have termed an extracellular filamentous matrix[6]. In transformed cells that are producing fibronectin, though at a lower rate, there is a failure to incorporate the glycoprotein into the extracellular matrix. There is also a similar failure to incorporate collagen into a cellular matrix in transformed fibroblasts[7]. The function of this protein, fibronectin, is thought to be related to cellular adhesiveness and perhaps thereby have some role in cell shape. Transformed cells are less adhesive to each other and to substrates when grown *in vitro* and upon addition of exogenous fibronectin there is a concomitant increase in adhesiveness and change in cell shape[8,9]. There are many examples of glucocorticoids modulating differentiation some of which include, liver[10], pancreas[11], mammary gland[12], retina[13] and myoblasts[14]. Recent work in the exocrine pancreas[11] suggests that glucocorticoids may induce specific enzymes without altering the level of general cellular proteins. Glucocorticoids have been shown to stimulate proliferation in growth arrested cells[15] and modify in a synergistic or inhibitory manner cellular responses to other hormones. We report here the effects of dexamethasone on modifying one phenotypic characteristic of cells, namely the occurrence of an extracellular filamentous matrix consisting of fibronectin and collagen. Based on the old hypothesis that transformed or malignant cells are arrested in differentiation, we consider development of the matrix a manifestation of the differentiated state of fibroblasts.

Using the peroxidase–antiperoxidase (unlabelled antibody enzyme) method of immunocytochemical localisation, transformed cells are shown to lack an extracellular filamentous

Table 1 DNA levels of SV40 transformed human fibroblasts

Days of culture	Control (μg DNA per plate)	Dexamethasone (μg DNA per plate) 10^{-7} M	10^{-6} M
0	11.06	—	—
1	24.89	25.58	23.51
2	51.86	52.55	48.40
3	99.57	98.88	102.33

Cells were grown as described in Fig. 1 and DNA assay was performed as described previously[14].

matrix which reacts with fibronectin antibodies at either the light (Fig. 1*a*) or the electron microscopic level (Fig. 1*b*). Following treatment with 10^{-8}–10^{-4} M dexamethasone a distinct clustering of fibronectin forms around and adherent to these cells (Fig. 1*c*, *d*). This matrix begins to form as early as 24 h after treatment and becomes more pronounced with time in the presence of dexamethasone and increased cell density. The localisation appears most extensive at concentrations of 10^{-7}–10^{-6} M dexamethasone, whereas at 10^{-9} M, staining intensity drops to control levels where very little staining is seen as on untreated cells. Light and electron micrographs were taken following 3 d of treatment with dexamethasone. Ultrastructurally the pericellular localisation of fibronectin is seen in dexamethasone-treated cultures (Fig. 1*d*) where none existed in untreated control SV40 transformed human fibroblasts (Fig. 1*b*). When the specific antibody is adsorbed with fibronectin before reacting with dexamethasone treated cells, no reaction is seen, indicating the specificity of the reaction (Fig. 1*e*, *f*).

Using the peroxidase–antiperoxidase method we also observed the failure of transformed cells to produce a collagen matrix as seen at the electron microscopic level (Fig. 2*a*). Normal cells produce a well defined matrix of collagen that can be detected ultrastructurally with either the unlabelled antibody–enzyme method or ferritin coupled antibody (Furcht *et al.*, in preparation). When the dexamethasone-treated transformed cells (10^{-8}–10^{-4} M) are examined with immunocytochemistry using antibodies to procollagen type I (which are known to cross-react with collagen type I) collagen is also observed to form a fibrillar matrix as seen at the electron microscopic level (Fig. 2*b*). The concordance of the development of a matrix of fibronectin and collagen is quite similar to ultrastructural observations we have made using double antibody labelling at the ultrastructural level on normal human fibroblasts (ref. 16, Furcht *et. al.* unpublished).

We were next concerned about the effect of dexamethasone on cell proliferation and examined the effects of dexamethasone on DNA accumulation per day in cultures and found no difference between dexamethasone-treated (10^{-7}–10^{-6} M) and control transformed cells (Table 1).

A recent study has examined the effects of various hormones on fibronectin of the murine continuous cell line 3T3. The studies of Chen *et. al.*[17] show that when murine 3T3 cells are grown in low serum they lose fibronectin-like protein from their surface. It was further suggested that epidermal growth factor (EGF) could specifically induce the formation of a fibronectin-containing matrix on serum depleted 3T3 cells and that this effect was blocked by addition of antibodies to EGF. A variety of other hormones, including cortisol, were also tested which had no effect on fibronectin on 3T3 cells grown in low serum[17]. Our data differs in that we very clearly show an accumulation of fibronectin and collagen in transformed human cells treated with dexamethasone.

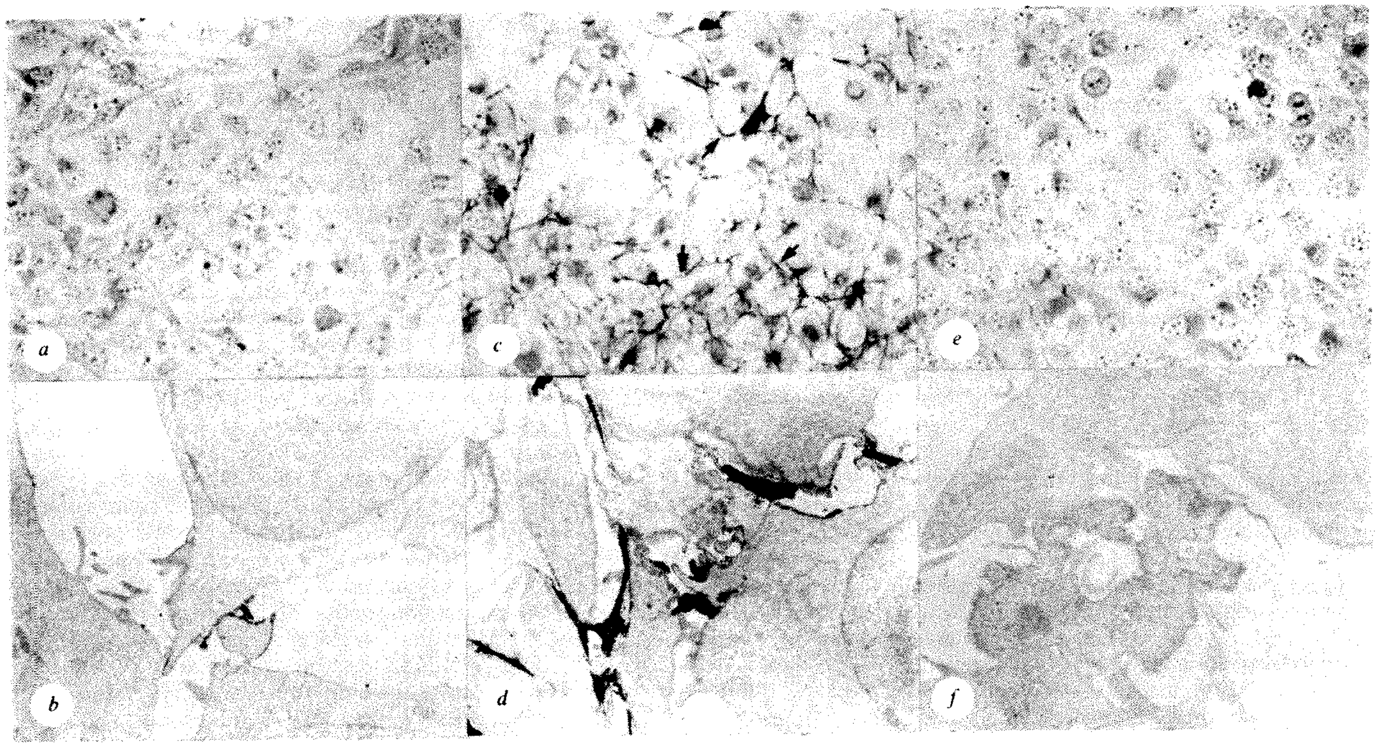

Fig. 1 Light (*a*,*c*,*e*) and electron (*b*,*d*,*f*) micrographs illustrating fibronectin accumulation on dexamethasone-treated SV40 transformed human fibroblasts. Cells are skin fibroblasts from a patient with Fanconi's syndrome which were transformed with SV40. The untransformed counterpart of the Fanconi fibroblasts has a normal distribution of fibronectin and procollagen type I identical to that seen in normal untransformed fibroblasts[16]. Cells were plated in Dulbecco's modified Eagle's medium (DMEM) with 10% fetal calf serum. After one day medium was changed to either regular DMEM with serum supplemented with 10^{-9}–10^{-4} M dexamethasone. Three days after the medium change samples were fixed with 1% glutaraldehyde (Electron Microscopy Sciences) in phosphate buffered saline for 20 min at 37 °C. Fibronectin and collagen were localised using our modification of the unlabelled antibody–enzyme method described previously[6]. Fibronectin adsorbed antifibronectin was used as the primary antibody for adsorption controls. Adsorption of fibronectin antibody is as described[6]. Results presented are of cells treated with 10^{-7} M dexamethasone. Light micrographs are taken of whole cells grown on Falcon tissue culture dishes after reaction with antibodies and immunocytochemical staining using an Olympus BH microscope equipped with an OM-10 automatic camera. Cells are then embedded *in stiu* with Epon, thin sections cut, and viewed without counterstaining in a Philips EM 300 as described[6]. *a*, No fibronectin localisation is apparent on transformed human fibroblasts grown in DMEM with serum (×130). *b*, Ultrastructural fibronectin localisation of transformed cells grown in DMEM with serum. Sparse staining is seen at sites of cell–cell contact and in general is lacking from the cell surface (×3,800). *c*, A matrix of fibronectin localisation surrounds cells which have been treated with 10^{-7} M dexamethasone (arrows, ×130). *d*, A dense staining is seen between cells which were treated with 10^{-7} M dexamethasone (×3,600). *e*, No staining is seen if dexamethasone treated cells are reacted with fibronectin adsorbed antifibronectin as the primary antibody (×130). *f*, Fibronectin adsorption control. No staining is seen at the ultrastructural level (×3,400).

It is important to consider a number of points of difference between work by other laboratories and our studies where we use: (1) human cells; (2) transformed cells which do not make fibronectin in a matrix normally; (3) normal culture conditions of medium and serum. This is to be contrasted to the rather artificially induced loss of fibronectin which occurs in serum deprived 3T3 cells[17]. As fibronectin is routinely present on 3T3 cells, reproduction of its loss with serum restriction could be subject to numerous difficulties. The cell type of a 3T3 is really unknown with speculation ranging from an endothelial cell[18] to a fibroblast, with also the potential to differentiate into an adipose cell with lipid accumulation (3T3-LI)[19]. Furthermore, 3T3 cells will form tumours if they are attached to a substrate and injected into immunosuppressed animals, raising the question of the propriety of using these cells as 'normal' cells[20].

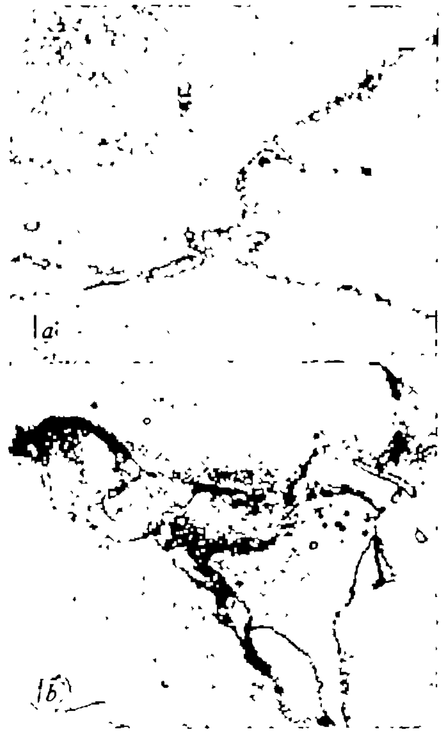

Fig. 2 Electron micrographs of thin sections illustrating immunocytochemical localisation of procollagen type I. Either affinity purified antibodies to procollagen I or the IgG fraction of antiserum to procollagen I was used with similar results. This antiserum also cross-reacts with collagen (Furcht *et. al.* submitted). Cells were treated as described in Fig. 1. *a*, Transformed human fibroblasts grown in DMEM lack a collagen matrix (×5400); *b*, transformed human fibroblasts grown in DMEM supplemented with 10^{-7} M dexamethasone form a collagen matrix identical to the fibronectin matrix seen in Fig. 1*d* (×5,400).

Several mechanisms should be considered for the dexamethasone stimulated accumulation of fibronectin and collagen associated on the cell surface of transformed human cells. First, recent studies have shown that the translatable mRNA for fibronectin and collagen is decreased in transformed cells[21] and perhaps dexamethasone is stimulating synthesis of this glycoprotein. Second, dexamethasone may effect whatever the processes are governing the polymerisation of fibronectin and adherence to cells so that more of the fibronectin and collagen synthesised remains or becomes adherent to cells. Based on the known interaction of fibronectin and collagen this might also involve collagen. Third, dexamethasone may modify the breakdown of fibronectin through modulating effects of hormones or proteases. With regard to this, surface associated fibronectin is very sensitive to protease degradation by trypsin and plasmin[22]. In relationship to this study, many transformed cells have elevated plasminogen activator levels[23] and other work has shown that dexamethasone will inhibit plasminogen activator levels in macrophages[24] and transformed cells[25]. Lastly, dexamethasone is known to modify prostaglandin biosynthesis[26], possibly by release of their precursor, aracadonic acid, or by some mechanism including transcription and translation. Therefore, prostaglandins in some unspecified way may be related to the dexamethasone-induced accumulation of fibronectin on transformed human cells.

In summary, if one postulates that the presence of fibronectin and collagen in normal substrate-attached fibroblast cells represents the differentiated state then the absence with transformation represents an arrest or blockade of differentiation. Based on this postulate it would then appear that dexamethasone treatment of transformed cells is capable of overcoming this arrest of differentiation as manifested in these two phenotypic traits, and results in the accumulation of fibronectin and collagen in transformed human cells.

Possible behavioural function for noradrenaline–acetylcholine interaction in brain

IN the peripheral nervous system, acetylcholine (ACh) acts on presynaptic muscarinic receptors to inhibit the release of noradrenaline (NA) from nerve terminals and by way of nicotinic presynaptic receptors to stimulate release[1]. A NA–ACh interaction has also been postulated[2–7] to occur in the central nervous system (CNS). Cholinergic agonists decrease the levels of NA in various brain areas[5,6], affect the release of NA in *in vitro* preparations[3,4] and have similar effects *in vivo* as measured by increased metabolites of NA (ref. 2). A reciprocal interaction, that of NA modulating ACh release in the CNS does not seem to occur, according to evidence[8] available at present. We report here that depletion of forebrain NA by intracerebral injection of the selective neurotoxin 6-hydroxydopamine (6-OHDA) almost completely blocks the catalepsy induced by cholinergic agonists such as pilocarpine and arecoline[9–12] and enhances the locomotor stimulation caused by the anticholinergic drugs scopolamine and atropine[13–15]. Although these actions have most usually been ascribed to an interaction with dopamine (DA) systems[16,17], our data show that functionally significant interactions between ACh and NA systems also occur.

Forebrain NA was depleted by intracerebral injection of the selective catecholamine neurotoxin 6-hydroxydopamine (6-OHDA)[18] into the dorsal bundle in which NA axons course from their cell bodies in the pontine nucleus locus coeruleus, to innervate wide areas of the forebrain such as cortex and hippocampus[19,20]. The extent of the depletion achieved is shown in Table 1 for a representative group of animals used in the following behavioural studies. Post-mortem assay[21] of endogenous amines revealed that cortical and hippocampal NA were depleted to less than 5% of control values, and that hypothalamic NA was also severely reduced, but with little effect on brain dopamine or descending NA systems.

The cataleptic effect of cholinergic agonists pilocarpine and arecoline is shown in Fig. 1. Each point represents a different group of 10 control and 10 lesioned rats, as the effects of arecoline are reported to change with repeated testing[11]. Catalepsy was measured by placing the animal's forepaws on a horizontal bar 7.5 cm above the ground and timing the period before the animal removed one or both paws to the ground. Saline-injected rats typically remove their paws within 10–15 s (Fig. 1). Both arecoline and pilocarpine induced considerable catalepsy in control animals, with times of up to 50 s or 100 s being required to remove the paws. Such catalepsy was almost totally blocked in the NA-depleted animals. Significant differences[22] were found between control and lesioned groups at all doses used, except 5 mg per kg of arecoline, which failed to produce catalepsy even in controls. The catalepsy induced by haloperidol, a dopamine-receptor blocking agent failed to differ at any dose[23] used, in spite of the induction of considerable catalepsy in both control and lesioned groups. This suggests that noradrenergic interaction is specific for cholinergic mechanisms, since the lesion fails to alter either dopamine levels (Table 1) or dopaminergic function as tested by haloperidol (Fig. 1).

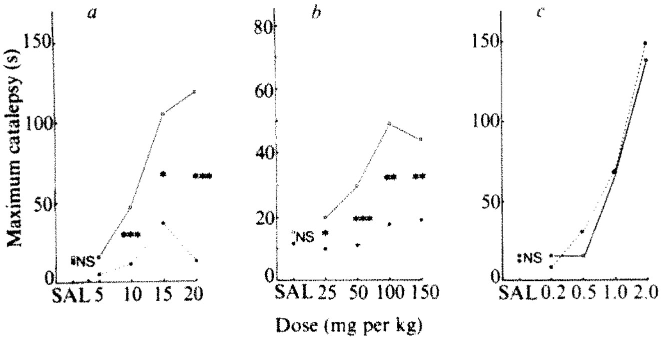

Fig. 1 Catalepsy induced in control and 6-hydroxydopamine lesioned rats. 4 μg 6-OHDA base (Regis, 6-OHDA HBr) dissolved in 2 μl of 0.9% saline with 0.2 mg ml^{-1} ascorbic acid, was infused through a 34 gauge cannula bilaterally at AP + 2.6 mm, ML ± 1.1 mm and DV + 3.7 mm from interaural zero, with the skull level between lambda and bregma. Controls received infusion of saline-ascorbic vehicle. Each point represents the mean of 10 control (□) or 10 lesioned (■) rats and fresh groups of animals were used for different points on the dose–response curve of a given drug. *a*, Arecoline; *b*, pilocarpine; *c*, haloperidol. The drugs were dissolved in 0.9% saline and injected intraperitoneally (i.p.). In the case of pilocarpine, 1 mg per kg methylscopolamine was given i.p. 30 min before the pilocarpine, to block the peripheral effects of the drug which interfere with catalepsy measurement. Control and lesioned groups differed at the following levels of significance using a two-tailed Mann-Whitney *U* test, *5%, **1%, ***0.1%, NS, not significant.

Table 1 Postmortem assay of amine concentrations in control and 6-hydroxydopamine lesioned rats

Region	Control ($n = 5$)	Lesioned ($n = 5$)	%*
Noradrenaline			
Hippocampus–cortex	264 ± 6	6 ± 1	2
Hypothalamus	2,240 ± 77	590 ± 87	26
Cerebellum	219 ± 12	271 ± 8	124
Spinal cord	255 ± 6	307 ± 12	120
Dopamine			
Striatum	13,170 ± 570	11,570 ± 1,190	88

Values are means in ng amine per g tissue, with s.e.m.

* Percentage of control concentrations remaining in lesioned tissues.

Cholinergic (muscarinic) antagonists such as scopolamine and atropine induced a mild locomotor stimulation. This was measured in photocell activity cages for a period of 2 h following drug injection. It can be seen from Fig. 2*a* and *b* that the representative doses used induced significant activity in controls compared with saline injections and that this waned with time. Although the initial locomotor stimulation over the first hour did not differ between controls and lesioned rats, an enhancement of the stimulant effect was evident in the second hour of testing. This was a central effect, since methylscopolamine, which does not cross the blood–brain barrier, failed to induce locomotor activity even in controls (Fig. 2*c*). Again, the noradrenergic interaction is specific to cholinergic systems, as the indirect dopamine agonist *d*-amphetamine, which is known to act through dopamine systems to cause locomotor activity[16,17], did not differ between control and lesioned groups (Fig. 2*d*).

The results suggest that cholinergic drugs modulate the activity of a noradrenergic system the function of which may be to influence the degree of behavioural arousal, as reflected by catalepsy at one extreme and locomotor stimulation at the other. Based on changes in sleep–wakefulness after 6–OHDA lesions, similar suggestions regarding the function of ascending noradrenergic neurones have been made by Lidbrink[24,25]. These behavioural findings also supplement biochemical observations that ACh can increase the release of NA in the CNS[2–7].

We tentatively propose the following model for the NA–ACh interaction. There is evidence for excitatory muscarinic receptors on noradrenergic cell bodies in the brain stem. It is known from microiontophoretic studies that the locus coeruleus has excitatory ACh receptors on its cell bodies[26], and may receive cholinergic input from neighbouring cell groups[27–29]. Cholinergic stimulation in the vicinity of the locus coeruleus has also been found to induce atonia and catalepsy[30–32]. In our model, the increased terminal release of NA that would result from the

0028–0836/79/0277–0396$01.00

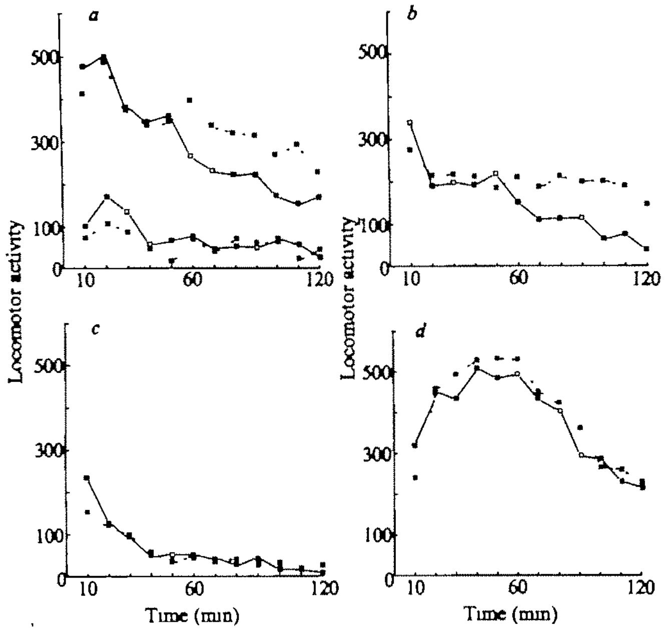

Fig. 2 Locomotor stimulant effect induced in control and 6-hydroxydopamine lesioned rats. Values are mean photocell beam interruptions per 10 min for 10 controls (□) and 10 lesioned (■) rats. *a*, 1 mg per kg scopolamine (upper lines), saline (lower lines). *b*, 10 mg per kg atropine. *c*, 1 mg per kg methylscopolamine; *d*, 1 mg per kg amphetamine. All drugs were dissolved in 0.9% saline and injected i.p. following 1 h of habituation to the photocell cages. Control and lesioned rats were compared statistically by a repeated measures analysis of variance.

cholinergic stimulation of the NA perikarya is a critical factor in producing the cataleptic response. Conversely, muscarinic antagonists would block the endogenous cholinergic activation of the NA cell bodies, thereby reducing the normal NA release, resulting in motor stimulation; a behavioural state opposite to catalepsy. The model might predict that dorsal bundle lesions would, by themselves, increase locomotor activity. That they do not, suggests that the anti-cholinergic drugs increase locomotor activity by actions on other neuronal systems in addition to the ascending NA projections. That is, rather than being due to decreased NA release alone, the locomotor stimulation induced by anticholinergic drugs seems to be a combined result of decreased NA release and actions on other, presently unspecified, systems. Similarly, although the ascending NA projections seem to play an essential part in muscarinic agonist-induced catalepsy, it is likely that concomitant cholinergic stimulation of other neuronal systems also contributes to this behaviour.

Our results demonstrate for the first time the existence of functionally important interactions between central cholinergic and noradrenergic mechanisms, suggest a role of the noradrenergic system itself and delineate a possible locus of this interaction.

Reduction in benzodiazepine receptors associated with Purkinje cell degeneration in 'nervous' mutant mice

HIGH affinity benzodiazepine binding sites which are both stereospecific and saturable[1–3] have recently been characterised in the mammalian central nervous system (CNS). The good correlations obtained between the binding affinities of a series of benzodiazepines and their potencies as anticonvulsants, anxiolytics and muscle relaxants strongly suggest that these sites may function as pharmacological receptors for the benzodiazepines[1,4]. Although both the gross anatomical[3,5] and subcellular distribution[6] of these sites have been described, the cellular localisation of these sites is not known, nor has a direct functional link been established between benzodiazepine binding sites and the neuropharmacological effects of these drugs. We now report that 'nervous' mutant mice, which undergo a selective loss of more than 90% of their cerebellar Purkinje cells during maturation[7,8], have a marked reduction in the number of cerebellar benzodiazepine receptors. This loss in benzodiazepine receptors seems to be confined to the cerebellum, and is not accompanied by an alteration in the affinity of the receptor for diazepam. These data clearly demonstrate the loss of benzodiazepine receptors in a cell type which has been shown to be both neurochemically[9] and electrophysiologically[10] sensitive to benzodiazepines, thus providing evidence that benzodiazepine receptors function in the pharmacological actions of these drugs.

Nervous (*nr*/*nr*), littermate (*nr*/+), and normal (+/+) mice of the C3HeB/FeJ strain (Jackson Laboratories), 9–11 weeks old, were used in these studies. Nervous mice were easily distinguished from littermates by a smaller size and characteristic ataxic gait. In addition, cerebellar weights were significantly reduced in the nervous mice when compared to littermate controls or normal mice (36 ± 2.5 mg compared with 55 ± 5.7 and 56 ± 5.0, respectively). No differences in forebrain weight were noted among the three groups. Mice were killed by decapitation, and the forebrains and cerebella dissected, weighed, and homogenised in 9 volumes of ice-cold Tris buffer (50 mM, *p*H 7.4). Incubation mixtures consisted of 40 μl of the 10% (w/v) tissue homogenate, 360 μl of Tris buffer, 50 μl of ^{3}H-diazepam (79.8 Ci mmol^{-1}, NEN, diluted in Tris buffer), and 50 μl of water or unlabelled diazepam (final concentration 3 μM). Nonspecific binding, defined as the amount of ^{3}H-diazepam binding to tissue in the presence of 3 μM diazepam, was less than 10% total binding using concentrations of diazepam near the K_d (compare refs 1, 11). Incubation conditions and

Table 1 Characteristics of ^{3}H-diazepam binding in 'nervous' (*nr*/*nr*), littermate (+/*nr*), and control (+/+) C3HeB/FeJ mice

	^{3}H-diazepam binding* (fmol per mg protein)		K_d (nM)		B_{max} (fmol per mg protein)	
	Cerebellum	Forebrain	Cerebellum	Forebrain	Cerebellum	Forebrain
Control (+/+)	415±10 (4)	424±16 (4)	4.4	4.6	957	1,110
Littermate (+/*nr*)	398±12 (4)	440±21 (4)	4.9	4.4	979	1,023
Nervous (*nr*/*nr*)	295±28 (4)†	390±24 (4)	3.9	4.5	668	1,075

Values are means ±s.e.m. with the number of animals in parentheses. Values for the K_d and B_{max} were obtained from the pooled tissue of seven mice per group.

* Binding obtained with 3.5 nM ^{3}H-diazepam.

† $P < 0.02$ compared to littermates, $P < 0.01$ compared to control mice.

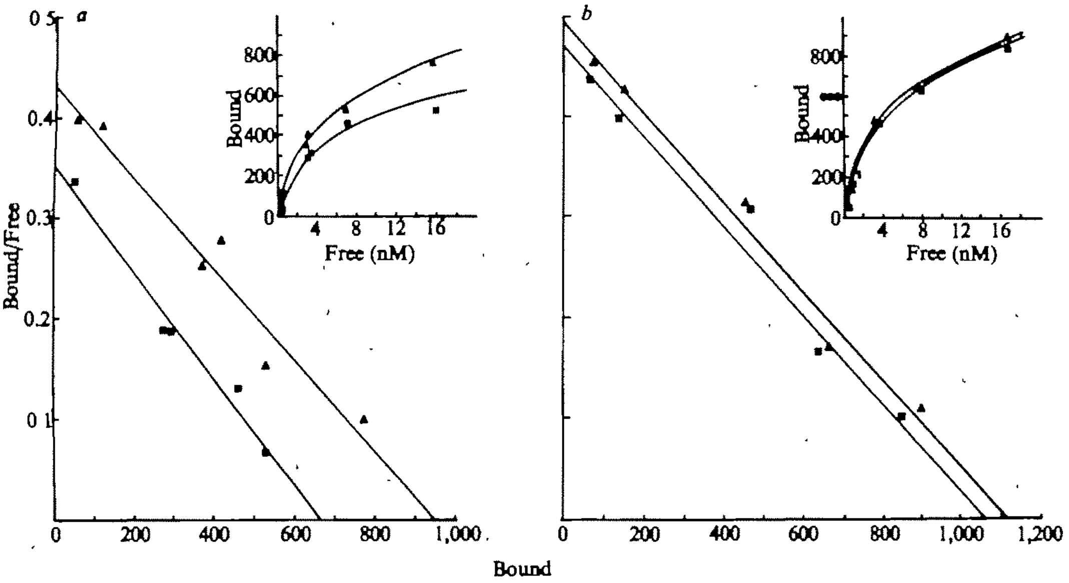

Fig. 1 Kinetics of ^{3}H-diazepam binding in nervous, littermate, and control mice: Scatchard analyses of binding in nervous (■) and control mice (▲) in *a*, cerebellar and *b*, forebrain homogenates. Insets: saturation plot. Scatchard and saturation analysis of littermate (*nr*/+) (■) and control (+/+) (▲) mice resulted in nearly superimposable curves (compare Table 1).

materials used for determination of ^{3}H-diazepam binding have been described elsewhere[2,11].

Preliminary experiments were performed using 3.5 nM ^{3}H-diazepam, as this ligand concentration would reveal differences in either receptor affinity or number. The binding of ^{3}H-diazepam in cerebella of nervous mice was reduced 25 and 29% when compared with littermate and normal C3HeB/FeJ mice ($P < 0.02$ and < 0.01, respectively) (Table 1). In contrast, no significant changes in ^{3}H-diazepam binding were observed in forebrain homogenates among the three groups (Table 1). Scatchard analysis (Table 1, Fig. 1*a*) of ^{3}H-diazepam binding revealed a marked reduction in the maximum number of benzodiazepine binding sites (B_{max}) in nervous mutant cerebella, with no apparent alteration in receptor affinity for ^{3}H-diazepam (K_d) (Table 1, Fig. 1*a*). Both the B_{max} and K_d for ^{3}H-diazepam binding were nearly identical among the three groups of mice in forebrain homogenates (Table 1, Fig. 1*b*). The reduction in benzodiazepine receptors observed in the nervous mice was manifest whether the results were expressed on a wet weight or mg protein basis.

Benzodiazepines have profound neurochemical and electrophysiological[10] effects on cerebellar Purkinje cells, presenting a model to assess the relationship between benzodiazepine receptors and the pharmacological effects of these drugs in a specific cell type.

The dramatic reduction in benzodiazepine receptors observed in the cerebella of nervous mice, which suffer a selective loss of Purkinje cells, clearly identifies these cells as possessing both a large number and high density of receptors, as Purkinje cells represent only a minute fraction of the total cerebellar neurone population. In contrast, 'weaver' mutant mice which undergo a selective loss of cerebellar granule cells, have been found to have no reduction in cerebellar benzodiazepine receptors (S. Snyder, personal communication). Heterozygous littermates (*nr*/+) have binding characteristics indistinguishable from control animals (+/+), demonstrating the necessity for the phenotypic expression of this defect to be manifest (degeneration of Purkinje cells) for a loss in benzodiazepine receptors to occur. The reduction in benzodiazepine receptors in cerebella of nervous mutant mice represents the first reported degenerative genetic disorder linked to altered numbers of receptors in the CNS. Furthermore, these observations strongly support a direct functional association between benzodiazepine receptors and the pharmacological actions of these drugs in the CNS.

Opiate antagonist reverses the cardiovascular effects of inhalation anaesthesia

THAT opiate receptors may mediate the action of inhalation anaesthetics is evident from the fact that intravenous injection of naloxone decreases the pain threshold in rats during inhalation anaesthesia[1,2]. But inhalation anaesthetics have not only analgesic and hypnotic properties, they also cause undesirable depression of the cardiovascular system. To investigate whether opiate receptors mediate the cardiovascular response to inhalation anaesthesia we perfused continuously the cerebro-ventricular system of both conscious and anaesthetised dogs with naloxone. Effects of anaesthesia with and without naloxone perfusion were compared for blood pressure, heart rate and baroreflex activity. The constant perfusion technique was adopted to avoid the drastic transients of naloxone brain concentrations which occur following intravenous naloxone application[3,4] and which might have masked the naloxone effects in recent reports[5–7]. We show here that (−)naloxone in contrast to (+)naloxone is capable of antagonising the circulatory effects of halothane anaesthesia from the fourth cerebral ventricle.

Eight dogs were prepared for perfusion of their cerebroventricular system under general anaesthesia. For perfusion of the fourth ventricle five dogs were used in whom stainless steel cannulae were permanently implanted, one into the rostral end of the fourth cerebral ventricle (inflow cannula) and another one into the cisterna cerebello-medullaris (outflow cannula) which drains the cerebral spinal fluid from the fourth ventricle. For perfusion of the third ventricle three other dogs were prepared with two cannulae located in each lateral ventricle. Additionally, both common carotid arteries were exteriorised into skin loops for direct blood pressure recording and also for testing of the carotid sinus reflex response to bilateral clamping of the loop arteries.

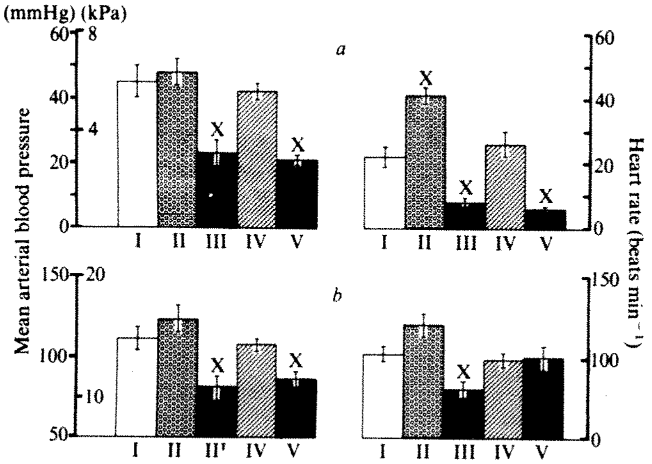

Fig. 1 Effects of continuous perfusion of the fourth cerebral ventricle without and with (−)naloxone at a concentration of 20 μg ml^{-1} on blood pressure, heart rate and carotid sinus reflex activity in conscious and anaesthetised (halothane) dogs. Perfusion periods are always 20 min. Halothane anaesthesia in combination with perfusion of the ventricle with Ringer's was maintained for 60 min. *a*, Response to clamping of carotid arteries: *b*, values before clamping. I, Conscious + Ringer, 20 min; II, conscious + naloxone, 20 min; III, anaesthetia 0.75 vol%, 60 min; IV, anaesthetia + naloxone, 20 min; V, anaesthesia 1.37 vol%, 20 min. Averages (± s.e.m.) from 10 experiments in three dogs. Differences relative to the controls (column I) were tested with Student paired *t*-test (X, $2P < 0.005$).

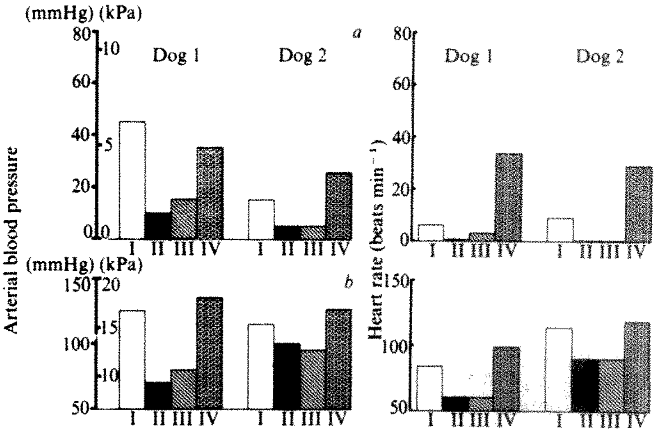

Fig. 2 Comparison of the effects of (+)naloxone and (−)naloxone at a concentration of 20 μg ml^{-1} perfused through the fourth cerebral ventricle on halothane-induced arterial hypotension, bradycardia and depressed carotid sinus reflex activity in two dogs. *a*, Response to carotid clamping; *b*, values before clamping; I, conscious; II–IV, halothane anaesthesia 0.72 vol%; II, 60 min; III, (+)naloxone, 20 min; IV, (−)naloxone, 20 min. There is hardly any effect from (+)naloxone but (−)naloxone promptly reverses the halothane effects to levels of the conscious state.

The dogs were trained to lie quietly and were unrestrained in the lateral position for the experiments in the conscious state. The actual experiments were performed 4 weeks after surgery. The animals participated for several months in the study and were familiar with the experimental environment. All the dogs were then repeatedly subjected to the experimental procedure described in the legend to Fig. 1. Ventricular perfusion (0.15 ml min^{-1}) was achieved with a microdrive single-channel push–pull pump (Braun Melsungen Unica B II). The restriction of the perfusion to the respective ventricles was verified by post-mortem dye distribution studies in each dog. The animals were anaesthetised with halothane at concentrations of 0.72–0.82 vol% in pure oxygen. The individual concentration was adjusted to render the animal analgesic as tested by pinching its nose with a haemostat.

Halothane was administered by a calibrated vapouriser adjusted to keep the end-expiratory concentration of the anaesthetic constant, which was verified by mass spectrometry (Perkins-Elmer MGA 1100). The responses of the animals to repeated bilateral carotid clamping of 1 minute duration were evaluated from continuous recordings of the heart rate and the arterial pressure.

In conscious dogs perfusion of the fourth cerebral ventricle with (−)naloxone results in a small increase in blood pressure and heart rate in association with unchanged reflex response of blood pressure but clearly augmented heart rate reflex (Fig. 1, columns I and II). During anaesthesia in combination with ventricular perfusion with Ringer's solution without naxolone (column III) all parameters are conspicuously reduced. But, most important, when (−)naloxone was added to the perfusate all parameters came back to the levels of the conscious controls. In fact, except for the heart rate levels, there are no significant differences present between the naloxone effects at the end of the 20 minute perfusion period (column IV) and the conscious state (column I). Finally, about twice the halothane concentration is necessary to antagonise the naloxone action (column V).

0028–0836/79/0277—0399$01.00

These observations suggest that structures bordering the fourth cerebral ventricle mediate the naloxone effect on inhalation anaesthesia. This is likely as (−)naloxone was found to be completely without influence on the circulatory responses in three dogs in whom the third and lateral cerebral ventricles were perfused under essentially the same protocol. Therefore, possible candidates for sites of interaction with naloxone are those opiate receptors located on the floor of the fourth cerebral ventricle and which continue into the periductal grey matter[8,10]. These receptors are located rather superficially and opiates bind intensively here[10], penetrating to about 800 μm after local application[11]. Thus, there are favourable conditions in our experiments for an interaction between naloxone and these receptors. Finally, proof for the specificity of these effects came from observations that (+)naloxone does not reverse the cardiovascular effects of halothane anaesthesia. This was shown in two dogs (Fig. 2) where perfusion of the fourth ventricle with (+)naloxone for 20 min had no discernible effects in the conscious state and did not reverse the arterial hypotension, the bradycardia and the depressed baroreflex activity of halothane anaesthesia maintained for 60 min. In contrast, all circulatory parameters promptly returned to the conscious control levels after a 20 min perfusion period with (−)naloxone.

Thus, it seems safe to conclude that naloxone antagonises the cardiovascular manifestations of inhalation anaesthesia by stereospecific binding with opiate receptors in structures bordering the fourth cerebral ventricle. Possibly, these are the same receptors which are located below the floor of the fourth cerebral ventricle from where opiates and morphinomimetic peptides trigger analgesia[13–15] and profound sedation with catalepsia[16,17].

Whatever the pharmacological mechanism behind the naloxone effect on inhalation anaesthesia might be, our observations strongly suggest that the opiate receptor system seems to be of importance for its mediation. If this is so, then it might be necessary to reconsider the currently held view that inhalation anaesthetics exert their pharmacological effects by nonspecific action on cell membranes. At least the cardiovascular manifestations of halothane anaesthesia are more likely to be the consequence of its interaction with opiate receptors in the brain rather than of nonspecific side-effects on the heart and/or blood vessels.

We thank Dr A. E. Jacobsen for supplying (+)naloxone. This work was supported by the Deutsche Forschungsgemeinschaft through the Sonderforschungsbereich Kardiologie 30 Düsseldorf.

Local anaesthetics inhibit tension development and Nile blue fluorescence signals in frog muscle fibres

FLUORESCENT DYES have been increasingly used to measure fluorescence intensity changes associated with changes in transmembrane potential in various preparations[1,2]. The use of these compounds is of particular interest in muscle fibres, as they can be used to detect potential changes occurring across membranes not directly accessible to electrical measurements, and possibly associated with excitation–contraction coupling processes. For example, muscle fibres stained with Merocyanine 540 and electrically stimulated, give an early fluorescent signal which has been thought to arise from surface and T-system membranes[3,4]. More interestingly, fibres stained with Nile blue A and electrically stimulated have been reported to give fluorescence signals probably arising from the sarcoplasmic reticulum membrane[2,5–7]. Optical retardation changes arising from this membrane system have also been reported[8,9]. These results seem to indicate the existence of an electrical response across the sarcoplasmic reticulum membrane which might be associated with calcium release from these structures during contractile activation. To test this possibility, we investigated and report here the effects of the local anaesthetics, procaine and tetracaine, on tension development and their comparison with the effects on the fluorescence signals generated in muscle

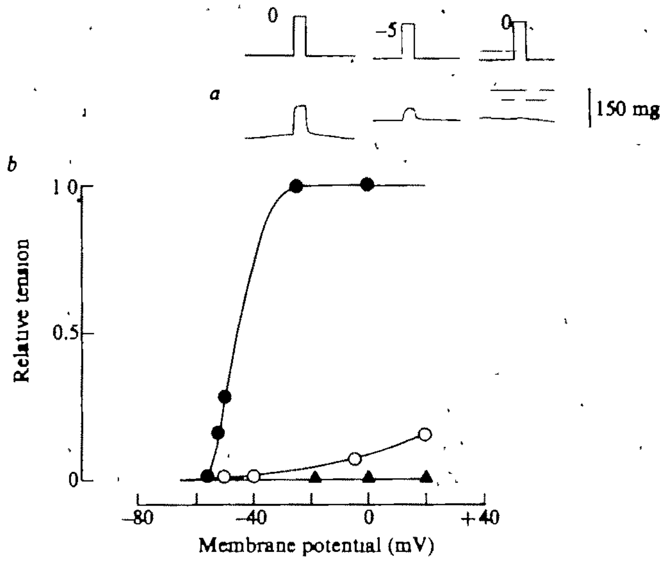

Fig. 1 Effect of tetracaine and procaine on the tension developed by three single fibres of approximately the same diameter (60–70 μm). The experiments used small bundles of short fibres (1–1.5 mm) dissected from the *Lumbricalis brevis* digit IV of the hindlimb of *Rana pipiens*. A two-microelectrode voltage-clamp technique was used to hold the membrane potential at a value of −100 mV and to apply depolarising pulses[13]. Tension developed by the clamped fibre was registered by means of an RCA 5734 transducer. The fibres were bathed in normal Ringer's solution containing 10^{-6} g ml^{-1} TTX to abolish sodium-dependent regenerative responses and improve the clamping conditions. *a*, From left to right, contractile responses (lower traces) to 1-s depolarising pulses (upper traces) obtained in normal Ringer, and in the presence of 5 mM procaine and 0.25 mM tetracaine, respectively. The level of the membrane potential during the pulse is given. *b*, The tension–voltage relationship obtained with the different pulses on the same fibres. Similar results were obtained with other fibres, although in the case of procaine the effect varied between different fibres. ●, Normal Ringer solution; ○, 5 mM procaine; ▲, 0.25 mM tetracaine.

fibres stained with Nile blue A. Procaine, and to a greater extent tetracaine, are thought to inhibit calcium release from the sarcoplasmic reticulum[10,11].

Figure 1 shows the tension–voltage relationships obtained with three different fibres in the absence of local anaesthetics, in the presence of 0.25 mM tetracaine, or in the presence of 5 mM procaine using voltage-clamp depolarising pulses. It can be observed that 0.25 mM tetracaine is a more effective inhibitor of tension development than 5 mM procaine. Furthermore, it is important that with tetracaine (>0.1 mM) tension was abolished in every fibre tested, whereas with procaine the effect varied considerably between fibres. This variability may account for the apparent discrepancy with the work of Thorens and Endo[12].

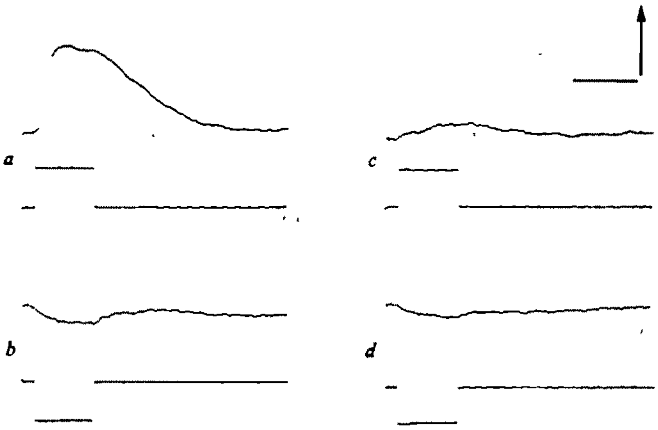

Fig. 2 Effects of tetracaine on the fluorescence signals in a stretched bundle of muscle fibres dissected from the semitendinosus muscle of *Calyptocefaleya gayi*, stained in Ringer plus 0.02 mg ml^{-1} Nile blue A (Allied Chemical). The chamber and optical arrangements were the same as previously described[4,6]. The bundle was stretched along a trough separated by Vaseline into a narrow central compartment (4 mm wide), where the bundle was illuminated, and two lateral compartments. Fibres in the bundle were depolarised by making the central compartment negative with respect to the lateral ones (positive currents) and hyperpolarised by reversing the polarity. To eliminate tension further and prevent regenerative action potentials, the compartments were filled with hypertonic 345 Tris Ringer solution (345 mM Tris-hydroxymethyl aminomethane-Cl, 1.8 mM $CaCl_2$ and 2.5 mM KCl). In each section, the upper trace shows the fluorescence signal and the lower trace the current pulse. In *a* and *b*, 345 Tris Ringer was used and in *c* and *d* 1 mM tetracaine was added to 345 Tris Ringer. *a*, *c* Correspond to depolarising current pulses and *b*, *d* to hyperpolarising current pulses. The magnitude of the arrow corresponds to a ratio of fluorescence change to basal fluorescence ($\Delta F/F$) equal to 2×10^{-3} for *a* and *b*, and 1.5×10^{-3} for *c* and *d*. The horizontal calibration bar corresponds to 100 ms. The excitation filter used in the optical record had a central wavelength of 625 nm and the collected light, at right angles, was filtered by a barrier filter that absorbed the excitation light (Schott RG-645). Temperature, 17 °C.

Figure 2 demonstrates the effect of tetracaine on the extrinsic fluorescence signal of muscle fibres stained with Nile blue. Fluorescence signals in response to depolarising (Fig. 2*a*) and hyperpolarising (Fig. 2*b*) current pulses indicate that, although of the same magnitude, the two pulses induce widely different fluorescence changes. The fluorescence change in response to the depolarising pulse is much the greater, suggesting the presence of a nonlinear membrane potential change. This potential change cannot be due to sodium-dependent regenerative responses, as the external solution was prepared without this cation. Figure 2*c*, *d* also shows that 1 mM tetracaine effectively abolishes the large component of the fluorescence change elicited by the depolarising pulses. The remaining signals behave more linearly for depolarising and hyperpolarising pulses, giving positive and negative fluorescence changes, respectively, with time courses similar to those recorded with Merocyanine 540 (ref. 4). The responses to hyperpolarising pulses are larger, probably due to increased membrane resistance in the presence of tetracaine.

Figure 3 shows the effect of procaine on the fluorescence activation curve. It is clear that in the absence of procaine, this

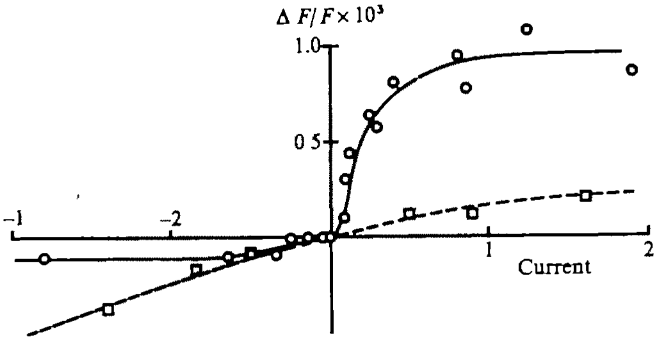

Fig. 3 Effect of procaine on the activation curve of the fluorescence signal. The points were obtained from an experiment in a bundle of fibres dissected from the semitendinosus muscle of *Calyptocefaleya gayi*, the procedure was the same as shown in Fig. 2 except that 10 mM procaine was used instead of tetracaine. The curve is a plot of $\Delta F/F$ against the current intensity of the depolarising and hyperpolarising pulses. The abscissa represents the size of the current pulse in arbitrary units. It must be stressed that the amount of current passed depends on the efficiency of the Vaseline seal between the three compartments (see legend to Fig. 2). The ordinates represent the peak values of the fluorescence signals. Circles correspond to experimental values obtained in 345 Tris Ringer and squares to values recorded in 345 Tris Ringer + 10 mM procaine. Temperature, 17 °C.

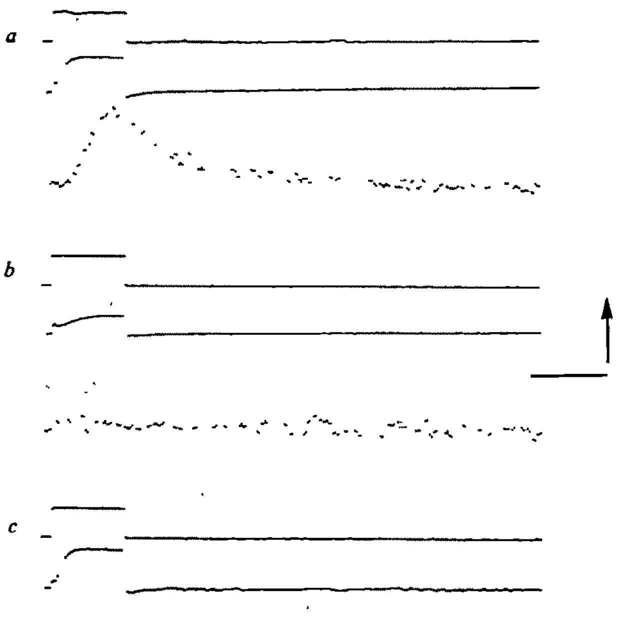

Fig. 4 Effect of tetracaine on the fluorescence signals and delayed rectification of voltage-clamped, cut single muscle fibres. The fibres were dissected from the semitendinosus muscle of *Rana catesbiana*. The techniques and optical arrangement used are described elsewhere[7] and are based on the work of Hille and Campbell[14]. Pool A, (see ref. 14) contained normal Ringer + 10^{-7} TTX. Pools C, B and E contained the following solution 120 mM K-aspartate; 5 mM ATP-Na_2; 1 mM $MgCl_2$; 2 mM EGTA-Tris; *p*H 7.2. In each section, the upper trace corresponds to voltage, the middle trace to the current, and the lower trace to fluorescence. *a*, Control records when the portion of the fibre in Pool A was immersed in Ringer + 10^{-7} M TTX. *b*, Records in Ringer + 10^{-7} M TTX + 1 mM tetracaine. *c*, Records after 30 min of recovery. The arrow corresponds to a $\Delta F/F$ of 7.2×10^{-3}, a voltage of 200 mV and a current of 13 µA. The horizontal calibration bar corresponds to 30 ms. Temperature, 20 °C.

curve has a steep S-shaped form reminiscent of the tension curve. On the other hand, in the presence of 10 mM procaine, the steep activation of the fluorescence for depolarising current pulses disappears, leaving only the more linear dependence probably arising at the surface and tubular membranes.

Finally, Fig. 4 shows the effect of 1 mM tetracaine on the fluorescence signal and on the membrane current of a single muscle fibre, voltage clamped, using the technique described by Hille and Campbell[14] but with a modified chamber which also allowed optical recording of fluorescence[6,7]. Figure 4*a* shows the voltage trace, membrane current and fluorescence trace for a fibre immersed in Ringers and 10^{-7} M tetrodotoxin (TTX). The fibre was clamped at about −100 mV and depolarised to 0 mV over 100 ms. It can be seen that tetracaine produced a complete blockage of the fluorescence signal. No linear component is observed, probably due to the small signal to noise ratio of the single fibre preparation. Figure 4*c* shows some recovery after 1 mM tetracaine was removed. Better recovery was observed when lower concentrations of tetracaine were used. The delayed current was blocked by the presence of tetracaine (Fig. 4*b*) and shows a good recovery on its removal (Fig. 4*c*). This current corresponds to the delayed K current whose kinetics are slowed and whose voltage dependence has been shown to be shifted by tetracaine[15]. Note that the recovery of the fluorescence signal does not parallel the recovery of this delayed current.

The results of these experiments show conclusively that procaine and tetracaine are effective in reducing or abolishing both tension development and the fluorescence signal in Nile blue A-stained muscle fibres. It has been postulated that this fluorescence signal is the optical manifestation of depolarisation of the membrane of the sarcoplasmic reticulum probably associated with calcium release[2]. Recent work carried out with local anaesthetics indicates that these agents are effective in blocking calcium release acting at the level of one of the last steps in the chain of events involved in excitation–contraction coupling. In fact, Almers and Best[11] have shown that tetracaine blocks contraction without affecting the charge movement; this indicates that calcium release can be inhibited one step further than the charge movement which is thought to link the electrical events of the transverse tubular membrane with those occurring at the level of the sarcoplasmic reticulum. The present experiments agree with this hypothesis and support the notion that the extrinsic fluorescence signal in Nile blue-stained muscle fibres may be derived from the sarcoplasmic reticulum membrane[2] and is associated with calcium release during contractile activation.

Pelvic structure and nature of reproduction in Multituberculata

RECENTLY prepared skeletons of Mongolian Late Cretaceous multituberculate mammals permit complete reconstruction of the pelvic girdle for the first time; its structure suggests that multituberculates may have been viviparous. Most important for these studies is a specimen of *Kryptobaatar dashzevegi*[1] from the Djadokhta Formation (?late Santonian and/or ?early Campanian), in which both the left and right pelvic halves, including equipubic bones, were preserved undistorted and articulated with part of the vertebral column (Figs 1 and 2). Three of the pelves in the same collection, belonging to three different genera are less complete, but have the same structure as the *Kryptobaatar* pelvis. The previously known multituberculate pelvis of the Paleocene *Eucosmodon*[2,3] was incomplete and although correctly reconstructed did not show some important details, that are now described.

Hopson[4] argued that viviparity was one of the last elements in a syndrome of reproductive adaptations to have evolved in mammals. We do not know when viviparity developed in multituberculates, but it should be remembered that the Late Cretaceous multituberculates that have been studied are some 130 Myr younger that their presumable Triassic ancestors[*]. If they were indeed viviparous, such a mode of reproduction in multituberculates was developed independently from that seen in therian mammals.

The sexes of individuals represented by the fossil pelves are unknown. All four pelves are of the same morphological pattern and for the purpose of the description that follows I assume that at least one was female and/or that pelvic sexual dimorphism was not an obvious feature in multituberculates.

As pointed out by Granger and Simpson[2], multituberculate pelves differ from those of other known mammals in being extremely narrow. The left and right pubes and ischia form a very acute angle and appear V-shaped from behind instead of meeting at an angle of about 180° as in most other mammals. In *Kryptobaatar* the opposite pubes are directed steeply ventromedially and meet at an angle of about 40°; the ischia meet at 45° anteriorly and progressively open up to 80° at the ischial arc. The ventral edges of the opposite ischia and pubes are very strongly fused and together form a prominent ridge. The height of the ridge is about 1 mm in *Kryptobaatar* and its length along the pubes and ischia is 15.2 mm (the bone is missing below the obturator foramen, probably due to damage, and only here has the ridge not been preserved). The greatest length of the pelvis is 32 mm. The posterior part of the pelvis in known multituberculates is strongly bent upwards as seen from the side and the ventral ridge of the fused ischia continues far dorsally which means that the free posterior edges of the ischia are short and the ischial arc is very small. The free edges of the ischia are about 3.8 mm long, and the estimated greatest width of the ischial arc is about 4 mm. The length of the pelvic ridge and degree of fusion indicate that the pelvis was rigid and could not have spread ventrally during parturition.

The nature and dimensions of the pelvic girdle bear on the important question of the size of the offspring or egg in multituberculates and so on their mode of reproduction. The cross sectional area of the passage above the ischial arc depends on the position of the tail, which is high in *Kryptobaatar.* Granger and Simpson[3] suggested that *Eucosmodon* had a large iliac-sacral angle of 45° or more. This angle appears to be about 35° in *Kryptobaatar*, leaving a distance of about 1–1.5 mm between the base of the tail and the upper border of the iscial arc. Allowing ~0.2 mm thickness for the soft tissues lining the pelvis, I estimate that if the multituberculates were viviparous, the maximum width of the head in a newborn *Kryptobaatar* could be no more than 3.4 mm. This is about 0.13 the width of the mother's

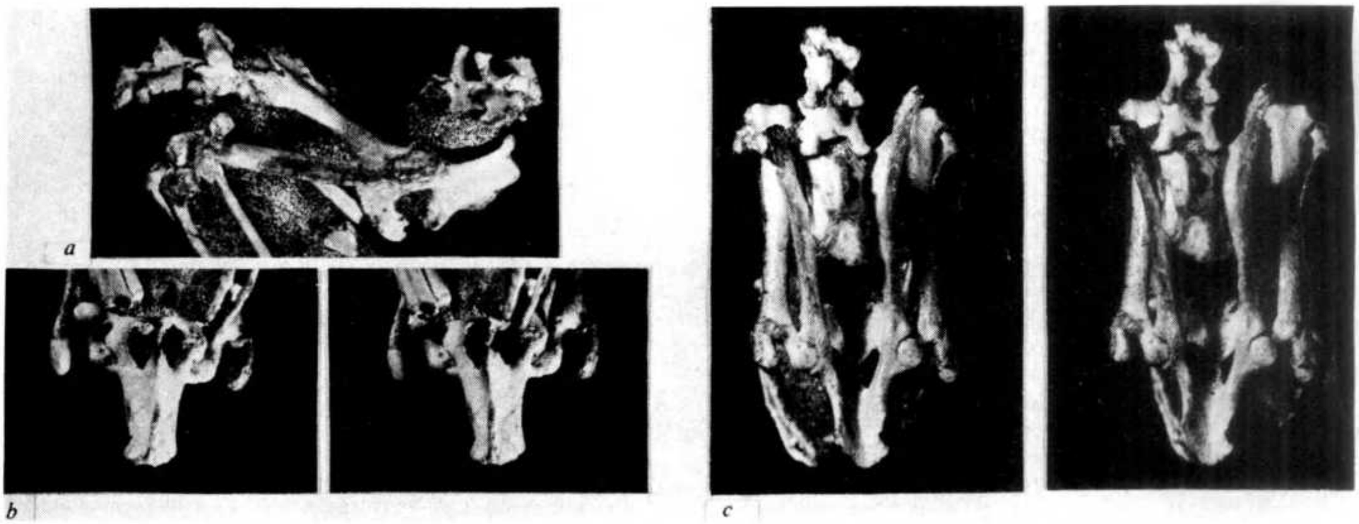

Fig. 1 *Kryptobaatar dashzevegi* pelvis. *a*, Left lateral view, photograph taken before final preparation; *b*, stereophotograph of the same specimen in ventral view, showing the ventral ridge; *c*, stereophotograph of the same specimen in dorsal view, the ischial tuber (present in *a*) was lost during preparation. ZPAL MgM-I/41, all ×1.5.

head compared with a ratio 0.33–0.4 in a rat and 0.45–0.5 in a mouse. There are no measurements available in the literature of the width of the head in newborn marsupials. But all marsupials weigh remarkably little at birth (all less than 1 g), even when the mothers are large[5].

As in *Kryptobaatar* the profile of the passage within the ischial arc is triangular, the space available for the passage of an egg of circular cross-section would be even less than 3.4 mm diameter. This would mean a smaller egg than any known cleidoic egg. In connection with the egg-laying habitat, the ischial arc in monotremes is wide and U-shaped[5] and relatively larger and structurally very different from the multituberculate ischial arc. I am therefore of the opinion that multituberculates were not oviparous, but viviparous with an extremely small neonate.

Apart from its relevance to reproductive habitat, the long immobile symphysis (which is relatively longer than in marsupials) and the well developed pelvic ridge may have a bearing to the mode of locomotion in *Kryptobaatar*. Some ungulates (for example *Antilocarpa* and *Tragulus*) have an immobile symphysis due to the presence of an unpaired interpubic bone and Wegner[7] argued that this is an adaptation in modern mammals associated with a capacity to jump. Perhaps multituberculates were also able to jump.

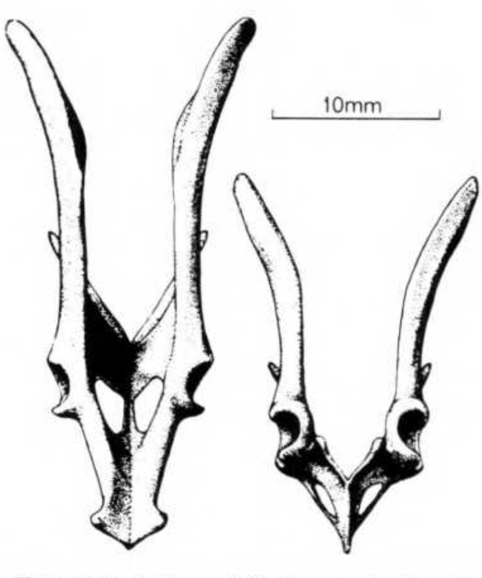

Fig. 2 *Kryptobaatar dashzevegi*. Right, reconstruction of pelvis in dorsal view. Left, reconstruction of the same in posterior view, showing size and shape of ischial arc.

Note added in proof: A. K. Lee (Monash Univ.) and L. Selwood (LaTrobe Univ.) have studied a marsupial *Antechinus stuarti* and found the mother's head width to be 15.4 mm, and the two newborn pouch young head widths were 1.6 mm and 1.5 mm, which is about 0.1 of the width of the mother's head (personal communication). This conforms with my estimate of 0.13 for multituberculates.

Isolation of the human placenta receptor for epidermal growth factor-urogastrone

EPIDERMAL growth factor-urogastrone (EGF-URO), a single-chain polypeptide of molecular weight ~6,000, found both in the mouse[1-3] and in man[4-7], is both a potent stimulant of cell proliferation and an inhibitor of gastric acid secretion. Specific membrane receptors for EGF-URO can be detected in various tissues including human placenta[8-11]. Although the mouse and human polypeptide sequences differ at 16 positions, they can share the same receptor site in human tissues[3,12]. There has been considerable recent interest in EGF-URO and its receptor, not only because of the potent mitogenic and acid-inhibitory actions of the polypeptide, but also because of the association of viral[13], chemical[14] and spontaneous[15] cell transformation with a specific reduction in cell receptors for EGF-URO. It is also believed that

0028–0836/79/0277—0403$01.00

EGF-URO and its receptor may be involved in the development, maintenance, and differentiation of tissues as diverse as the lens[16], the palate[17] and the keratin layer of skin[18]. In experiments aimed at the isolation of the membrane receptor for EGF-URO, we have observed that, unlike the receptor for insulin[19], but like the muscarinic receptor for acetylcholine[20], the EGF-URO receptor loses its ligand recognition property following solubilisation with detergents. We therefore developed an affinity-labelling technique using glutaraldehyde, that can covalently crosslink the receptor with ^{125}I-labelled EGF-URO before solubilisation[21]. Independently, Das and coworkers have developed a photoaffinity-labelling technique that can also be used to radiolabel the EGF-URO receptor before solubilisation[22]. Here we report the success of both our previously described glutaraldehyde crosslinking technique[21] (using ^{125}I-EGF-URO for receptor labelling) and of a newly developed photoaffinity-labelling technique (using a photolabile ^{125}I-EGF-URO crosslinking reagent) to identify the EGF-URO receptor in human placenta membranes and to effect the isolation of the affinity-labelled receptor by affinity chromatography using lectin and murine EGF-URO antibody–Agarose columns.

Table 1 Affinity chromatography of ^{125}I-photoaffinity-labelled EGF receptor

Lectin	Eluting sugar	Radioactivity (%) Unadsorbed	Sugar eluate	Sugar-urea eluate	Residual
WGA	*N*-Acetylglucosamine	94.8	4.4	0.7	0.1
Lens culinaris	α-Methylmannoside	95.8	3.6	0.4	0.2
Concanavalin A	α-Methylmannoside	93.0	3.0	2.5	1.4
Phytohaemagglutinin	*N*-Acetylgalactosamine	95.5	1.1	2.0	0.9
Ricinus communis	Galactose	99.7	0.2	0.0	0.0
Peanut Lectin	Galactose	99.8	0.1	—	0.1

The EGF-URO receptor of placenta membranes was labelled using the photoaffinity method as described in Fig. 1 After solubilisation with Nonidet P-40 and clarification by ultracentrifugation, aliquots of the labelled solubilised membranes were applied to 200 μl lectin–Sepharose 4B columns (5 mg lectin per ml beads) equilibrated with 0.1% Nonidet P-40, 0.2 M NaCl, and 50 mM Tris-HCl, *p*H 7.5. The columns were washed with 20–30 column volumes of buffer (flow through) and then eluted with an appropriate lectin-specific sugar at 0.2 M. The plant lectin columns were subsequently eluted with sugar-containing buffer, made 4 M in urea. Finally, the radioactivity remaining on the column was measured. The figures represent the percentage, relative to the total radioactivity applied, of the radioactivity in the unadsorbed fraction, in the fraction eluted with sugar, in the fraction eluted upon addition of urea, and the amount remaining on the column after the final elution (residual).

When placenta membranes were crosslinked covalently with ^{125}I-labelled EGF-URO, either by the glutaraldehyde method or by the photoaffinity technique, electrophoretic analysis of the solubilised membrane protein in polyacrylamide slab gels revealed an identical autoradiographic pattern (Fig. 1); two major components (bands I and II) of apparent molecular weights 180,000 and 160,000 could be detected. The relative amounts of the two components present seemed to vary somewhat from one preparation to another, as indicated by differences in the intensity of the autoradiographic patterns. When crosslinking was carried out in the presence of an excess of unlabelled EGF-URO, the labelling of bands I and II was virtually abolished, whereas that of other barely detectable components remained unchanged.

Previous data[15,21,23,24] suggested that the EGF-URO receptor is a glycoprotein. We observed that a variety of lectin–Agarose columns could adsorb selectively the major labelled components present in the crude solubilised membrane preparation (Table 1 and Fig. 1), enabling selective desorption with the appropriate lectin-specific sugar to take place. The wheat germ agglutinin (WGA)-agarose column proved to be the most effective, resulting in a 30-fold receptor purification using crude soluble preparations as starting material. Analysis of the specific eluate from the WGA column revealed the presence of a third minor radioactively-labelled component of apparent molecular weight 48,000.

The amino terminus of murine EGF-URO provides the only free primary amine and is the site of the coupling of the photoaffinity label. Because the remainder of the molecule is unchanged, we hypothesised that the anti-EGF-URO antibody would still recognise the EGF-URO moiety after crosslinking it to the putative receptor. The material eluted from the WGA-agarose column was therefore applied to an anti-EGF-URO antibody–Agarose column. Approximately 40% of the applied radioactivity was adsorbed to the column and more than 95% of the protein was unadsorbed. Elution of the antibody–Agarose column with 10% v/v formic acid, yielded the same components, detected autoradiographically, that had been adsorbed by the WGA–agarose column (Fig. 1, columns *f* and *h*). In the experiment depicted (columns *e*–*h*), the preparation of labelled receptor contained principally band II and a small proportion of band I; both bands I and II were adsorbed by the antibody affinity column. The amount of protein present in the eluate could not be detected (absorbance at 280 nm). When the same amount of WGA–agarose column eluate was applied to an agarose affinity column prepared with pre-immune rabbit serum, >95% of the radioactivity was unadsorbed and the characteristic autoradiographic pattern of the formic acid eluate previously observed with the antibody–agarose column was not detected. Similarly, when crude soluble membrane proteins were purified by WGA-agarose affinity chromatography, labelled with ^{125}I, and subsequently applied to an anti-EGF-URO antibody–agarose column and to pre-immune rabbit serum–agarose column, >95% of the radioactivity was unadsorbed. When the formic acid eluate was subjected to electrophoresis, bands in the region of I and II were not detected.

Because of the high specificity of the binding of EGF-URO to membrane-binding sites[8–12,16,22] and because of the correlation of this binding with the biological activity of EGF-URO in certain cell systems[8,10], it is reasonable to assume that binding components detected in this and previous studies represent the cellular receptor involved in EGF-URO action. It is of particular importance that the two independent methods of radiolabelling the receptor yield identically labelled components, as indicated by electrophoretic analysis. It is perhaps surprising, as previously discussed[21], that the glutaraldehyde–borohydride technique does not yield a wide spectrum of crosslinked components, but probably links ^{125}I-labelled human EGF-URO to its binding site in a relatively restricted membrane environment. Important is the fact that, using the conditions we describe, the photoaffinity label does not, following generation of the nitrene, alkylate a large number of protein constituents, as is observed in intact cells[22]. Because the two methods of radiolabelling the receptor are chemically quite dissimilar and

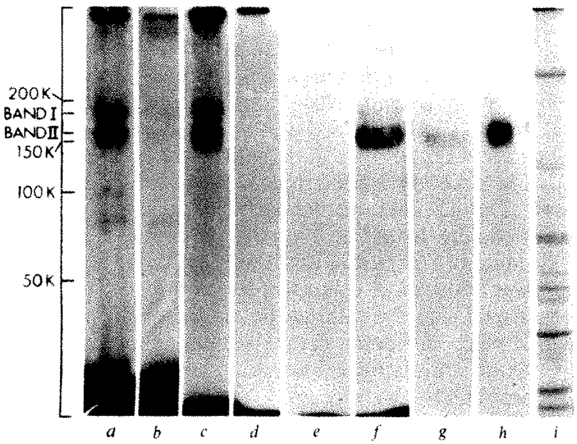

Fig. 1 Electrophoretic analysis and autoradiography of soluble protein from ^{125}I-EGF-URO affinity-labelled placenta membranes. Columns *a* and *b* represent the analysis of protein that was affinity-labelled either in the absence (*a*) or presence (*b*) of excess unlabelled mouse EGF-URO using the glutaraldehyde-borohydride method described previously[21]. Briefly, human placenta membranes (0.5 mg ml^{-1}), prepared by differential centrifugation, were equilibrated (40 min, 23 °C) with ^{125}I-labelled human EGF-URO, washed with ice-cold buffer, resuspended, crosslinked with the addition of glutaraldehyde (4.2 mM; 40 min, 4 °C), reduced with sodium borohydride (16.7 mM, *p*H 9.0, 30 min, 4 °C), solubilised (1% w/v Nonidet P-40, Particle Data Laboratories), clarified by centrifugation (200,000 *g*, 30 min) and the soluble supernatant analysed by polyacrylamide gel electrophoresis using 7.5% gels and the method of Laemmli[27]. Labelled protein was detected by autoradiography of fixed, dried gels. Columns *c* and *d* represent the analysis of soluble protein from membranes that were first photoaffinity-labelled either in the absence (*c*) or presence (*d*) of excess unlabelled mouse EGF-URO. The photoactive ^{125}I-EGF-URO derivative was prepared by first iodinating mouse EGF-URO, using the Iodogen (Pierce) procedure as described previously[29], with 5 μg of mouse EGF-URO and 2 to 3 mCi carrier-free ^{125}I in 200 μl of 0.3 M phosphate buffer, *p*H 7.6. After the addition of ^{125}I (40 s), the reaction mixture was transferred to a foil-covered vial containing 800 μl 0.1 M phosphate buffer, *p*H 7.6. Aliquots were removed for measurement of the amount of radioactivity present and of the incorporation of ^{125}I into EGF-URO. The volume was made up to 2 ml with buffer and *N*-succinimidyl-6-(4′-azido-2′-nitrophenylamino) hexanoate (SANAH; Pierce) was added in the dark (30 μl of 1 mg ml^{-1} in dimethylsulphoxide) to the stirred solution. The reaction (30 min, 24 °C) was terminated by the addition of 0.5 ml of 50 mM unbuffered lysine HCl. The product was stored in the dark at 4 °C and used without further purification. Photoaffinity-labelling was achieved by incubating the SANAH derivative of ^{125}I-labelled mouse EGF-URO (330 pmol) with membranes (40 ml of 1 mg membrane protein per ml in 0.1 M NaCl, 50 mM Tris HCl, *p*H 7.6) for 40 min at 23 °C in the dark and then activating the azide group by illumination (two 200 W incandescent bulbs at 10 cm) at 4 °C for 10 min. Labelled membranes were collected and washed twice by centrifugation (48,000 *g* for 20 min), solubilised (4 mg ml^{-1} in 0.5% Nonidet P-40) and the clarified extract (200,000 *g*, 30 min) analysed by gel electrophoresis with visualisation of labelled protein by autoradiography. Columns *e* and *f* represent the analysis of soluble photoaffinity-labelled protein which was applied to a 300 μl wheat germ agglutinin (WGA)-Sepharose 4B column (4 mg WGA ml^{-1} beads) prepared by the method of March *et al.*[28] and equilibrated with buffer (0.1% w/v Nonidet P-40, 0.2 M NaCl in 50 mM Tris HCl, *p*H 7.6). Column *e* represents the analysis of the unadsorbed fraction; column *f* represents the adsorbed material that was eluted from the WGA-Sepharose column with 0.2 M *N*-acetylglucosamine (NAG) in buffer. Columns *g* and *h* show the analysis of protein that was first specifically eluted with NAG from WGA-Sepharose and then applied to an anti-mouse EGF-URO antibody-Sepharose 4B column. Column *g* represents the unadsorbed fraction; *h* shows material that adsorbed to the column and was eluted with 10% v/v formic acid. Column *i* shows the protein pattern of untreated placenta membranes stained with Coomassie Blue. Bands I and II represent the major affinity-labelled proteins; the left hand scale shows the calibration of the gel according to the molecular weight markers *β*-galactosidase (130K), phosphorylase A (94K), bovine serum albumin (68K) and pyruvate kinase (54K).

yet yield identical results, we conclude that the risks of misinterpretations inherent in either crosslinking procedure have been minimised.

The apparent molecular weights of the two principal constituents detected in the present study are in excellent accord with our own previous data[21] and with the data of Das *et al.*[22], who detected a photoaffinity-labelled substituent of apparent molecular weight of 195,000 in mouse cells. We did not, however, detect, in the placenta membrane, the constituent of molecular weight ~100,000 which we observed in rat liver membranes using the glutaraldehyde-borohydride technique[21]. Detection of more than one receptor constituent cannot be readily explained. The most likely explanation, however, is that the two major constituents represent molecules that are closely related to one another either by a degradative (for example, receptor processing) or synthetic (precursor-product) process. These possibilities may explain the variation in the relative amounts of the two major constituents that we have observed from one membrane preparation to another. It is of interest in this regard that the affinity labelling of the *β*-adrenoreceptor also yields two principal constituents[25]. No components analogous to the 'processed' receptor constituents detected by Das *et al.*[26] in an intact cell system seem to be detected by our techniques in the placenta membrane preparation.

The present work demonstrates directly the glycoprotein nature of the EGF-URO receptor. It also demonstrates a novel method for purifying receptors utilising anti-ligand antibodies and provides a scheme for the large scale isolation of receptors which, like the EGF-URO receptor, seem to lose their ability to recognise ligand after solubilisation and thus are not amenable to purification by hormone-agarose affinity chromatographic procedures.

The molecular nature of heat-labile enterotoxin (LT) of *Escherichia coli*

ALTHOUGH *Escherichia coli* is part of the natural flora of the mammalian gut, certain strains cause a cholera-like disease in humans and young farm animals[1,2]. These *E. coli* strains carry at least two plasmid-mediated determinants of virulence[3,4]. One class of plasmids, called Ent, codes for the synthesis of one or more enterotoxins[3]. These toxins disrupt the fluid balance in the gut resulting in a net efflux of fluid and electrolytes from the gut epithelial cells[1]. The heat-labile toxin (LT) and cholera toxin have been shown to be identical in their modes of action[5] and also to be immunologically similar[6,7]. Although cholera toxin has been purified and characterised[8], it has proved difficult to purify LT and it is not yet fully characterised. Molecular weight estimates for LT range from 20,000 to over 100,000 (refs. 9–11). We report here investigations of the molecular nature of LT carried out by studying an LT gene isolated using recombinant DNA technology[12]. Using *E. coli* minicells[13], the proteins encoded by the LT gene were identified and the structure of LT was found to be similar to that of cholera toxin.

Recently we reported the isolation of an LT gene on a 5.8×10^6-MW DNA fragment[12]. Using *in vitro* deletion techniques, this DNA fragment has been reduced in size to MW 1.2×10^6 and has been linked to the R-plasmid pBR313 (W.S. D., D. M. Gill and S.F., in preparation). This new plasmid, EWD299, encodes for LT as measured by the *Y*-1 adrenal cell tissue culture assay[14]. Proteins specified by the chimaeric plasmid were identified using minicells as an *in vivo* protein synthesising system. Minicells do not contain chromosomal DNA but may contain plasmid DNA molecules. The plasmids are transcribed and the mRNA is translated in minicells.

Plasmid-encoded proteins from minicells were radioisotopically labelled by incubating purified minicells with ^{35}S-methionine or ^{14}C-amino acid mix. The total minicell proteins were separated by SDS-polyacrylamide gel electrophoresis (PAGE) and the plasmid-specified proteins were identified by autoradiography. EWD299 was found to encode about 12 distinct proteins, (Fig. 1 track *a*). The LT gene-specified proteins were identified among these labelled proteins using an antiserum prepared against a crude preparation of LT and a *Staphylococcus aureus* strain containing protein A[15]. The protein A on the *S. aureus* binds antibodies without disrupting their active sites. Tertiary complexes of protein A, antibody and antigen can be formed and these aggregates can be separated from the unreacted antigens in the minicell lysate (see Fig. 1 for details). A 26,000-MW protein (Fig. 1, track *e*), was shown to bind nonspecifically to *S. aureus* cells and has been identified as β-lactamase[16]. Two other proteins of molecular weights 11,500 and 25,500 were found to be complexed in the presence of the anti-LT serum (Fig. 1 track *d*). These results may be interpreted in two ways. First, only one of the proteins is actually LT and the other protein was present in the extract used to raise the antiserum. On the other hand, LT may be a multimeric toxin composed of two distinct protein species.

Cholera toxin is a multimeric toxin composed of two structurally and immunologically distinct proteins[8]. Antisera can be prepared directed specifically against the adsorption protein, subunit B. This subunit binds the holotoxin to the target cell membrane, facilitating the activity of the A subunit, and has no toxic activity on its own. Antiserum prepared against subunit B was used in the *S. aureus* experiments and the results are shown in track *b*. Both the 11,500 and the 25,500-MW proteins were present, suggesting that LT is composed of at least two distinct proteins, one of which is immunologically related to the B subunit of cholera toxin. These data indicate that LT is present as a multimeric toxin intracellularly, as two proteins were isolated with an antiserum directed against a single protein. Track *c* contains a minicell preparation from an experiment using a holocholera toxin antiserum. Again, both the 11,500 and the 25,500-MW proteins are present.

Cholera toxin is composed of three polypeptides. The B subunit migrates in SDS-PAGE at an apparent MW of 11,000 (data not shown). Subunit A is composed of a 24,000-MW polypeptide linked by a disulphide bond to a 5,500-MW polypeptide[17]. The subunit structure we have found for LT is similar to that of cholera toxin but there are notable differences. The small subunit of LT, the 11,500-MW protein, is about 500 daltons larger than the B subunit of cholera toxin. Furthermore, there is no evidence of disulphide linkage in the 25,500-MW LT subunit. It has been shown that subunit A of cholera toxin has adenyl cyclase stimulating activity and a similar activity in crude LT preparations has been seen[20]. We also have enzymatic and genetic evidence that demonstrates an adenyl cyclase stimulating activity for the 25,500-MW protein (Dallas, Gill and Falkow, in preparation).

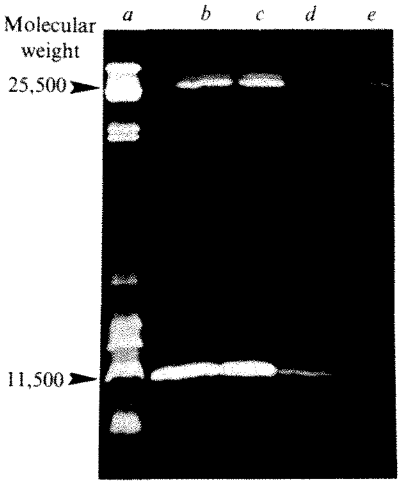

Fig. 1 Identification of the LT proteins. Minicells containing EWD299 were isolated and plasmid-encoded proteins were labelled by incubating the minicells with ^{35}S-methionine[16]. A minicell cytoplasmic fraction was prepared as follows. Labelled minicells were frozen and resuspended in phosphate buffered saline, 1% Triton X-100, 5 mM EDTA (PBSTE). Lysozyme was added to 100 μg ml^{-1} and the preparation was sonicated. The lysate was cleared at 35,000*g* for 30 minutes and the supernatant was used for the antisera experiments. An aliquot of antiserum was added to the supernatant and the solution was incubated at room temperature for 30 min. Formalised *S. aureus*[15] was added and the mixture was incubated for an additional 30 min. *S. aureus*–antibody–antigen complexes were isolated by pelleting the solution through 1 M sucrose in PBTSE (1,000*g*). The pellet was boiled for 3 min in final sample buffer (10% glycerol, 5% β-mercaptoethanol, 3% SDS and 0.0625 M Tris, *p*H 6.8). Aliquots were electrophoresed on 10–15% gradient SDS-polyacrylamide gels[19]. The gels were dried onto filter paper and autoradiographed for 3–14 d. Track *a*, total minicell lysate; track *b*, anti-cholera B subunit serum; track *c*, anti-cholera toxin serum; track *d*, anti-LT serum; track *e*, no anti-serum added.

The primary structure of cholera toxin subunit B is established[18]. It should be possible to determine the primary structure of the 11,500-MW LT protein by nucleotide sequencing and to compare the amino acid sequences of these two proteins. Analysis of the primary structure of the two large toxin proteins may give further information concerning the evolution of these two similar enterotoxins.

We thank D. G. and D. J. Evans for heat-labile toxin antiserum, R. A. Finkelstein for subunit B and holocholera antisera. This work was supported by a grant from the National Institutes of Allergy and Infectious Diseases AI10885-07.

W.D. was supported by PHS award GM 07270 from the National Institute of General Medical Services.

Escherichia coli lac operator mRNA affects translation initiation of *β*-galactosidase mRNA

THE primary function of the start of a message (mRNA for a specific polypeptide) is to ensure the correct initiation of translation. Little is known about the factors determining the frequency of translation or indeed if its variability is important in the total expression of genes. Recently, an analysis was introduced that allows calculation of *in vivo* frequencies; it was shown that the *in vivo* initiation rates of the first and last messages of the *lac* mRNA differ by fivefold[1]. Different initiation frequencies could be effected, in part at least, by a sequence of three or more nucleotides about 8 to 15 residues upstream from the initiating AUG codon that is complementary to a purine-rich sequence at the end of the 16S ribosomal RNA[2,3]. Four such complementary nucleotides are residues 8–11 before the AUG start of the *β*-galactosidase (EC 3.2.1.23, *β*Gase) message. Mutants for this sequence are not available, but there is a whole series for a more distant region—22 to 34 nucleotides before the AUG: the *lac* O^c mutants. Here we show that certain of these mutations affect the rate of translation as well as the stability of this message.

Lac O^c mutants are defective for binding repressor protein to the *lac* operator. The more than 800 O^c mutants of Smith and Sadler[4] could be grouped into seven classes defined by *P* values (ratio of basal to induced *β*Gase levels). So far, representatives of each class have been identified as single-base change mutants[5] which map in the initial sequences of the *lac* mRNA[6] (Fig. 1). This primary effect on the repressor–operator binding does not explain other changes in *β*Gase expression. The amount of fully induced *β*Gase (zero repression) differs between strains, with some accumulating more enzyme, and some less, than does the O$^+$ parent[4,7]. Thus, it seemed possible that the translation initiation frequency was affected by these mutations.

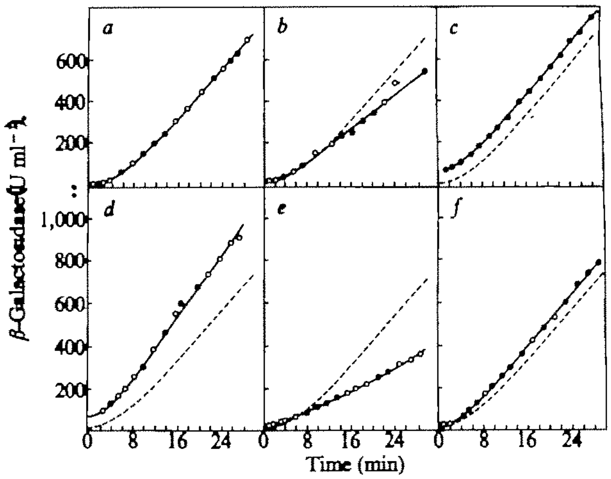

Fig. 2 The induction of *β*Gase in various *E. coli* HfrC, *proC*, *metB*, *strS lac* O^c mutants and O$^+$ parent strain described by Sadler and Smith[4]. Bacteria were grown at 37 °C in M9 inorganic salts[26] with methionine (to 50 μg ml^{-1}), proline (to 50 μg ml^{-1}), casein hydrolysate (to 0.4%) plus 0.2% glycerol and were induced at zero time by the addition of isopropyl-*β*-D-thiogalactoside (IPTG) (to 0.5 mM) after addition of cyclic AMP (to 2 mM) at −2 min to minimise catabolite repression. Samples were removed at the indicated times and brought to 0 °C, and metabolism further inhibited by addition of chloramphenicol (to 50 μg ml^{-1}) plus sodium azide (to 10 mM). The rate of *β*Gase synthesis was calculated after 15 min of induction when it had reached its maximum. At this time there were 2.6×10^8 viable bacteria per ml with 32 μg RNA per ml. *a*, Parent strain O$^+$, *b*, strain IIIa, *c*, strain IIb; *d*, strain IIa; *e*, strain IIIb; *f*, strain Vb. The synthesis of *β*Gase in the parent strain (*a*) is reproduced for comparison as a dashed line in each panel.

Rates of *β*Gase synthesis during full induction are required to estimate translation-initiation frequencies. Of six representative strains shown in Fig. 2, IIb and Vb are similar to the parent, IIa gives stronger induction, and IIIa and IIIb give weaker. The ratios of induction rates seen here between strains are similar to the ratios of fully induced enzyme levels observed earlier[4,7]. The turnover number for *β*Gase is ~400,000 U mg^{-1} (refs 1, 8) and its tetrameric molecular weight is 465,000 (ref. 9). With these values and the viable cell count determined at the time of induction measurement, the synthesis of *β*Gase monomers per s

Fig. 1. The nucleotide sequence of the start of the *lac* mRNA as determined by Maizels[6]. The base substitutions expected in the mRNA from the changes in DNA sequence of the various O^c strains, determined by Gilbert *et al.*[5] are shown. The wavy line designates the initiation codon for the start of the *β*Gase polypeptide and the underlined AGGA could be a potential recognition site for UCCU at positions 3–6 from the 3′ end of the 16S rRNA. The sequences derived from the right side of the operator DNA, as defined by protection from repressor binding[24], as well as the shorter length defined from the minimal stretch that can form stable repressor complex[25], are shown by the horizontal bars. The dashed lines show the residues protected from RNase degradation by a ribosome initiation complex. The longer segment is the maximum length protected against RNase T1 and the shorter is the minimum length protected against RNase A[13]

0028-0836/79/0277—0407$01.00

cell is calculated in Table 1, column 2. The parent HfrC strain produces 19 monomers per s cell, strain IIa 25, and at the other extreme, IIIb only nine.

Three parameters of gene expression combine to give these final rates of enzyme synthesis at any instant. (1) The number of message molecules producing finished polypeptides, (2) the rate of translation initiation, and (3) the rate of ribosome movement. The first parameter is the most difficult to measure. It is derived from the total z mRNA mass which is given most accurately by dividing its rate of synthesis (S) by its decay constant (k) (refs 1, 10) and then converting mass to numbers of completed molecules[1].

The rate of z message synthesis is derived from the fraction of 30 s pulse-labelled RNA that is z-specific in these fully induced cells (about 1.5% after correction[1] for hybridisation efficiency). As these strains double every 50 min, they contain 1.7 copies of the *lac* operon per cell[1]; this gives about 2.5 s between transcription initiations and 100 nucleotides between RNA polymerases (column 3). These mutations do not affect the rate of transcription initiation. None of the strains show functional or mass decay slower than that of the parent ($t_{1/2} = 1.5$ min) (Fig. 3), but decay in IIa, IIIa, Va, Vb and VIa is significantly faster ($t_{1/2} < 1.2$ min) (column 4).

After subtracting the mass of nascent z mRNA, the number of completed molecules can be calculated (column 5, and Table 1 legend). Combined with the rate of ribosome movement (about 40 nucleotides per s per ribosome from the 80 s induction lag[11,12]) the translation initiation rate (column 6) and resultant density of ribosomes can be calculated. The loading frequency of the parent averages 4.9 s between initiations to give 176 nucleotides between ribosomes. Six O° strains differ: IIa, Va, Vb and VIa average only 3 s between translation initiations (110 nucleotides between ribosomes), whereas IIIb and IVb initiate significantly more slowly (8 s between initiations for strain IIIb to give 288 nucleotides between ribosomes.) There is a threefold range of initiation rates between these strains.

Mutations in the fastest-loading strains are not clustered; IIa and Va/Vb are 12 residues apart, and in fact, define the outer boundaries of the set. Conversely, the two mutations that give slower-loading are adjacent. All of these mutations lie outside the RNA region protected from RNase A digestion by the initiating ribosome[13] (Fig. 1). The IIa mutation is located about the diameter of a ribosome from the AUG start (assuming 4 Å per residue).

A possible secondary structure of the operator RNA can be considered (Fig. 4). Its free energy can be calculated from studies with synthetic polyribotides[14–17]. The favourable free energy from base pair stacking is about −8.6 kcal mol^{-1} at 25 °C, and the unfavourable energy from the constraints in closing the loop[14] would be about +7 kcal mol^{-1} (for a 9-base loop closed by AU) to give a net −1.6 kcal mol^{-1} at 25 °C. This structure should 'melt' at >25 °C; the T_m can be estimated from the enthalpy and entropy values that were also measured for the model polymers. Using values from two laboratories[14,15] yields a T_m of 45 °C or 58 °C. Note that the T_m of a monomeric duplex (with hairpin loop of this size) is much higher than is the T_m of the same duplex formed from two separate strands (see Fig. 4 in ref. 14). While the melting profile may be quite broad, it seems likely that most of the molecules are in this configuration at 37 °C.

What is striking is that the fast-loading strains IIa, Va, Vb give very similar decay and loading values and share the common feature of disrupting the single GC bond in the stem (Fig. 4) to generate a stem whose energy is now limited to the lower four AU pairs (−3.6 kcal) and has considerably less energy than the +8 kcal in the 11-base loop. If the secondary structure were a hindrance to ribosome loading, then such base changes would

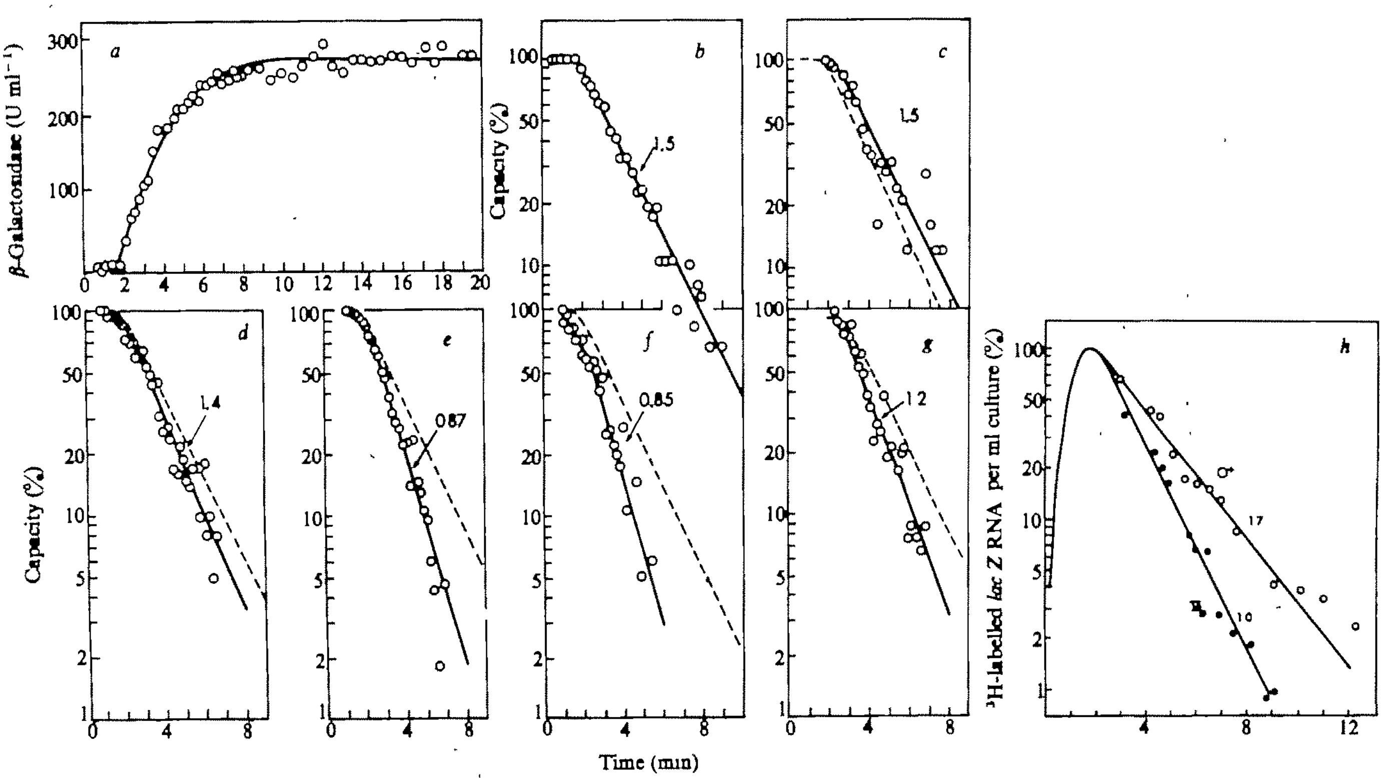

Fig. 3 Functional and mass decay of βGase message in various *E. coli lac* O° mutants and the O$^+$ parent. Cultures were induced at zero time and sampled as described in Fig. 2 except that rifampicin (to 300 μg ml^{-1}) was added at +30 s to inhibit further transcription initiations. *a*, The burst of βGase from parent strain O$^+$; *b*, the loss of capacity to synthesise enzyme[27] from the data in (*a*). The remaining panels only show this latter variable for each strain induced and sampled in the same way. *c*, Strain IIb; *d*, strain IIIb; *e*, strain Vb; *f*, strain IIIa; *g*, strain IIa. The half lives (min) are shown and the curve of the parent strain (*b*) is reproduced for comparison in each panel. Panel (*h*) shows the mass decay of βGase message in strain Vb and parent O$^+$ strain; [5,6-^{3}H]uridine (to 33 μl ml^{-1} and 2 nmol ml^{-1}) was added at −30 s and rifampicin as above. RNA extracted from each sample was reacted with denatured λp*lac*5 DNA to form hybrid and the hybrid fraction times the amount of ^{3}H-RNA per ml gives the relative amount of *lac z* message shown[28]. The half lives (in min) are shown.

Table 1 Expression of β-galactosidase gene in operator constitutive mutants of *E coli*

1 Strain	2 βGase synthesis monomers per cell per s*	3 Nucleotides per RNA polymerase	4 mRNA half-life(s) (ln 2/*k*)	5 Completed mRNA molecules per cell†	6 Time between translation initiations (s)‡

Exponentially growing bacteria were induced by addition of cyclic AMP (to 2 mM) and IPTG (to 0.5 mM) and rates of enzyme and message synthesis measured between 12 and 20 min after IPTG addition At 15 min there were 2.6×10^8 cells per ml with 32 μg RNA per ml. Divide amounts per cell by 1.66 to give amounts per chromosome. All values refer to the βGase gene, mRNA or enzyme

* There are four monomers per βGase to give 4.8 molecules of βGase per s per cell in strain O$^+$.

† The total mass of *lac z* mRNA/cell is made of: (*a*) completed *z* molecules that are not decaying, (*b*) completed *z* molecules in various stages of decay, and (*c*) incomplete or nascent molecules (some are also decaying), still on DNA and thus not releasing finished polypeptides at that instant. The mass of the nascent class can be estimated from *S* and subtraction from the total mass gives the mass of functioning molecules. The distribution between decaying and non-decaying species is derived from the 5′ to 3′ nature of the decay process[1] and leads to the actual numbers of functioning molecules per cell (column 5) (see ref. 1) The total *lac* mRNA per cell varies from 1.5×10^{-10} μg (three strains including O$^+$) to 1.0×10^{-10} μg (four strains) There are 52 nascent molecules per O$^+$ cell, 50 complete and 40 completed but decaying The number of completed molecules that are not decaying is the most variable with the faster-decaying strains (IIa, IIIa, Va, Vb, VIa and VIIa) containing only about 28 molecules per cell.

‡ All experiments were performed on three different cultures of each strain. The experimental values (*S*, *k*, and induction rate) represent averages with maximum deviations of ±10% each. If the experimental values for a strain were all in error by 10% 'in the same direction', the final computer-derived initiation frequency (column 6) would be in error 30% in that direction— insufficient to account for the 300% range of values.

decrease the probability of its existence and thus increase the frequency of successful collisions.

The slower initiation rates of strains IIIb and IVb might also reflect the presence of the secondary structure of Fig. 4. First, note that IVb would generate two more base pairs and a five-membered loop to increase the structural stability to $\Delta G = -5.1$ kcal mol^{-1} at 25 °C from -1.6 kcal mol^{-1}. However, IIIb would not affect the structural stability and suggests another possible explanation. Independent studies in this laboratory have shown an involvement of RNase III activity in translation initiation of βGase. βGase mRNA from strain AB301-105 (ref. 18) is much less competent to form *in vitro* initiation complexes than is βGase mRNA from the *rnc*$^+$ parent[19]. The RNase III recognition sequence has been defined in detail in four of six T7 RNA sites[20,21], and the four are similar: cleavage between U and G and release of terminal fragments UUAU$_{OH}$ and pGAU. Cleavage of *lac* RNA between the residues U and G at positions 6 and 7 would liberate UUGU$_{OH}$ plus pGAG. As indicated above, opening the loop would lower the T_m of the duplex. If this is a site for RNase III cleavage, then IIIb and possibly IVb, might load ribosomes more slowly because the enzyme could no longer disrupt the structure. The hypothesis is being tested by *in vitro* experiments.

Strains VIb, IIIa, IIb and VIIa give the parental O$^+$ initiation frequency, and they all map in the upper part of the loop structure and should not alter it. Thus, 9 of the 11 characterised *lac* O^c mutants give expression that is consistent with the structure shown in Fig. 4. Strains VIa and IVa give inconsistent results. It is possible that they were assigned incorrectly or contain secondary mutations in either *lac* DNA or the genetic

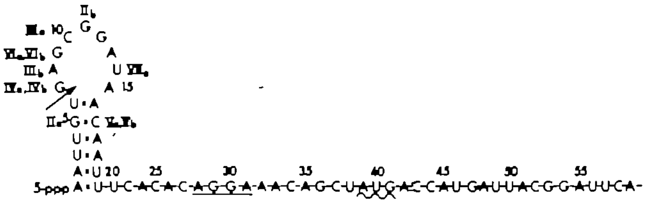

Fig. 4 A possible configuration of the *lac* mRNA[6]. The AGGA and AUG are designated as in Fig. 1. The arrow indicates a putative RNase III target.

background. In strains IVa and VIa expression of the distal *lac* galactoside acetyltransferase (GATase) message and βGase message change in parallel, suggesting some nonspecific effect, perhaps on all messages. In contrast, for example, the extremely fast βGase message decay in strain Vb is not paralleled by faster than normal (O$^+$) decay of GATase message (data not shown).

Thus, the major observation presented here is that the RNA region more than 21 residues before an AUG start is important for translation initiation as well as message stability. These two processes show no obvious correlation here (Table 1); however, other studies suggest a causal relationship between decay and loading frequency[1,22], perhaps obscured in these base change mutants because the vulnerability of the specific decay target must also be a function of the primary base sequence itself. A role of RNA secondary structure in initiation has been suggested, not only in the well known RNA phage translation, but in recent speculation concerning internal initiation sites of the *lac i* mRNA[23] which have potentially base-paired regions proximal to them. However, this is the first report to relate mutations in a potential secondary structure to measured changes (threefold range) in initiation frequencies.

We thank Dr Jack Sadler for providing strains, Dr Temple Smith for unpublished observations and Louis Lim for a computer program for translation initiation frequencies. This investigation was supported by NIH research grant 1 RO1 AI 13492. V.J.C. is supported by NIH training grant 5T32 CA 09129.

Double-stranded DNA stereoselectively binds benzo(*a*)pyrene diol epoxides

BEFORE it can exert its mutagenic and carcinogenic activities[1,2] benzo(*a*)pyrene (BP) requires metabolic activation and it is widely considered[3–5] that the initiating event in these processes is covalent binding to DNA. The predominant form of the activated hydrocarbon is a diol epoxide[6–11], of which four possible isomers are (+) and (−) enantiomers of 7β,8α-dihydroxy-9α-10α-epoxy-7,8,9,10-tetrahydro-BP (*anti*-BP diol epoxide) and (+) and (−) enantiomers of 7β,8α-dihydroxy-9β,10β-epoxy-7,8,9,10-tetrahydro-BP (*syn*-BP diol epoxide). Enzymatic formation of the (+) *anti* and (+) *syn* configurations have been reported elsewhere[12,13]. We have shown that the racemic (±) *anti*-BP diol epoxide forms two stable covalent adducts each with the exocyclic amino groups of deoxyguanosine, deoxyadenosine and probably deoxycytidine[14]. We report here that we have now resolved the enantiomers of (±) *anti*-BP diol epoxide and reacted the optically pure hydrocarbons with DNA. Each enantiomer reacts with the exocyclic amino group of deoxyguanosine to form a pair of diasteriomers in a ratio which depends on the secondary structure of the nucleic acid. The (+) enantiomer reacts preferentially or asymmetrically with deoxyguanosine in double stranded DNA but the two enantiomers react equally with the same position in single-stranded DNA. The basis for the stereoselective binding is unknown but may involve formation of sterically orientated physical complexes before covalent attachment of the hydrocarbon to DNA. The mode of binding in the deoxyadenosine sites, on the other hand, must be different, as the (+) and (−) enantiomers react equally in either single- or double-stranded DNA.

The (±)BP diol epoxide was synthesised as described elsewhere[15,16]. ^{3}H-(±)*anti*-BP diol epoxide was synthesised by an adaptation of the method used by McCaustland *et al.*[17]. The (+) and (−) enantiomers of *trans*-7,8-dihydroxy-7,8-dihydro-BP were resolved by published methods[18] and converted to (−) and (+) *anti*-BP diol epoxides, respectively. Either racemic (±) *anti*-BP diol epoxide or the optically pure (>96%) (+) or (−) enantiomers were reacted with calf thymus or ΦX174 DNA. After removal of unreacted hydrocarbon the DNA was enzymatically hydrolysed to hydrocarbon–deoxynucleosides and the stable covalent adducts isolated by Sephadex LH-20 column chromatography. The adducts were then separated by reverse-phase high-pressure liquid chromatography (HPLC). Of the stable covalent adducts formed, 95% were recovered as determined by radioactivity measurements. Figure 1*a* shows the HPLC profile obtained by reacting racemic (±) *anti*-BP diol epoxide with native calf thymus DNA after hydrolysis and Sephadex LH-20 column chromatography.

We have previously identified adducts numbered 1–5, 7 and 8 (ref. 14). Peak number 1 was a tetraol hydrolysis product of the *anti*-BP diol epoxide, whereas adducts 2 and 4 represented deoxycytidine-derived products. The contribution of peak 4 to the total adduct formation was variable as it co-chromatographed with one of the tetraol hydrolysis products of the diol epoxide. Adducts 3 and 5 were reaction products with deoxyguanosine, and numbers 7, 8 and 9 were deoxyadenosine products. With native calf thymus DNA the deoxyguanosine adducts represented 90% of those formed. However, the distribution of adducts obtained depended on the reaction conditions used and was primarily a function of DNA secondary structure, that is, the more denatured the polymer the higher the proportion of adenine adducts obtained.

We have previously reported[14] that the pair of deoxyguanosine adducts (peaks 3 and 5) obtained from reaction of racemic (±) *anti*-BP diol epoxide with native calf thymus DNA were probably diastereomers, as their high resolution mass spectra were identical and their circular dichroism spectra were of similar shape but inverted. We have now demonstrated this result for both the deoxyguanosine and deoxyadenosine products by resolving the enantiomeric diol epoxides and carrying out adduct formation individually with DNA. The results of these reactions are shown in Fig. 1*b*, *c*. These profiles indicate that the (+) enantiomer reacted to form deoxyguanosine adduct 5 and deoxyadenosine adducts 7 and 9, whereas the (−) enantiomer resulted in deoxyguanosine adducts 3 and 6 and deoxyadenosine adduct 8. Peaks 6 and 9, although not previously

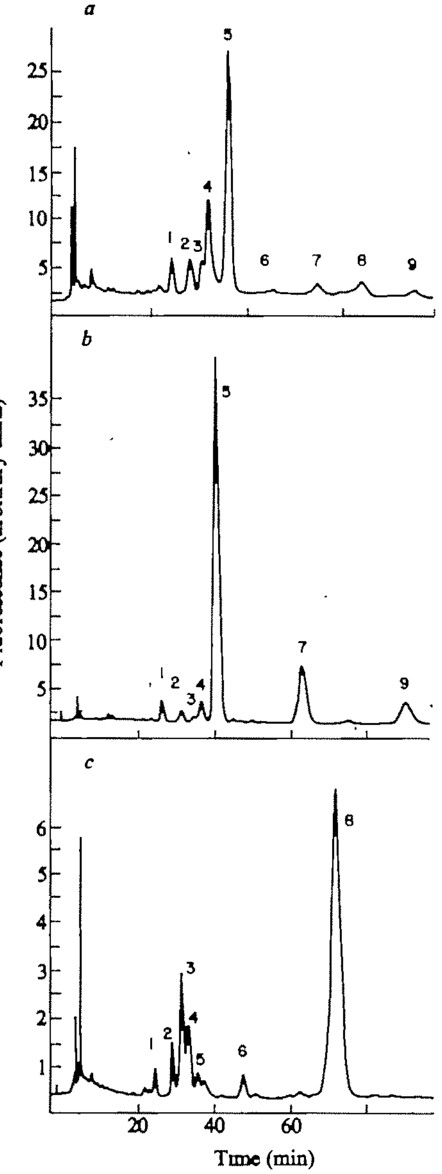

Fig. 1 Tritium-labelled racemic (±) *anti*-BP diol epoxide or the resolved enantiomers were incubated with 1 mg deproteinised native calf thymus DNA at an initial concentration of 1 hydrocarbon per 250 nucleotides in 0.01 M sodium phosphate, *p*H 7.5, for 1 h at 37 °C. Unbound hydrocarbon was removed by ethyl acetate extraction and repeated isopropanol precipitation of the DNA until zero time blanks contained <3% of the tritium of incubated samples. Routinely, incubated samples resulted in a modified DNA of 1 hydrocarbon per 8,000 base pairs The diol epoxide-treated DNA was converted to hydrocarbon–deoxynucleosides and deoxynucleosides by treatment with DNase II, spleen phosphodiesterase and alkaline phosphatase. The hydrolysed sample was applied to a Sephadex LH-20 column and the free deoxynucleosides and enzymes eluted with water. The hydrocarbon–deoxynucleosides were quantitatively recovered with methanol and analysed by HPLC[14]. The elution profiles represent DNA reacted with: *a*, racemic (±) *anti*-BP diol epoxide; *b*, (+) *anti*-BP diol epoxide; *c*, (−) *anti*-BP diol epoxide. The identity of adducts 1–9 are discussed in the text.

identified, correspond to deoxyguanosine and deoxyadenosine adducts, respectively, as indicated by field desorption mass spectrometry[19].

Reaction of nucleophiles with *anti*-BP diol epoxide has been shown to occur exclusively at the benzylic C-10 position, with a preference for *trans* addition[20-22]. It is possible, however, that DNA secondary structure could influence the stereochemistry of the epoxide ring opening to give *cis* addition products as well. As the D-deoxyribose moiety of each nucleoside unit within the DNA polymer contains an asymmetrical centre at C-1, the reaction of a racemic mixture of (±)BP diol epoxide would be expected to yield a maximum of four diastereomeric products per alkylation site ((+) diol epoxide per D-deoxyribose, each with *cis* or *trans* addition at C-10 of the hydrocarbon). Reaction of the metabolically produced (+) *anti*- and (+) *syn*-BP diol epoxide[12,13] with the exocyclic amino groups of guanine, adenine and cytosine in DNA would result in 12 possible diastereomeric covalent adducts. Recent indirect evidence[23] suggests that the (−) *anti* and (−) *syn* diol epoxides may also be made *in vivo*, and if this is the case then there would be 24 possible products by reaction of the four hydrocarbons with the three exocyclic amino groups in DNA. We obtained two resolvable deoxyadenosine diastereomers by reaction of the (+) *anti*-BP diol epoxide with DNA (adducts 7 and 9), which were probably the result of *cis* and *trans* addition of the adenine exocyclic amino group. Reaction of the (−) diol epoxide yielded peak 8 which by recycle chromatography consisted of two partially resolvable components. Each had virtually identical mass spectra[19], indicating that they were deoxyadenosine exocyclic amino adducts. Thus, the (−) enantiomer reacted with deoxyadenosine to give two adducts, in agreement with the above predictions.

Three hydrocarbon–deoxyguanosine adducts were observed in the reaction of racemic (±) *anti*-BP diol epoxide with DNA—peaks 3, 5 and 6. Peaks 3 and 5 correspond to the major and, presumably, *trans* addition products of (−) and (+) diol epoxide with N^2-deoxyguanosine, respectively. Peak 6, derived from the (−) enantiomer, was a relatively minor component and may correspond to either an exocyclic amino *cis* addition product or to a different guanine adduct with alkylation at some other site. For deoxycytidine only two adducts (peaks 2 and 4) were observed. The relative contributions of (+) and (−) *anti*-BP diol epoxide to these two peaks was difficult to assess, as peak 4 also contained varying amounts of a tetraol hydrolysis product.

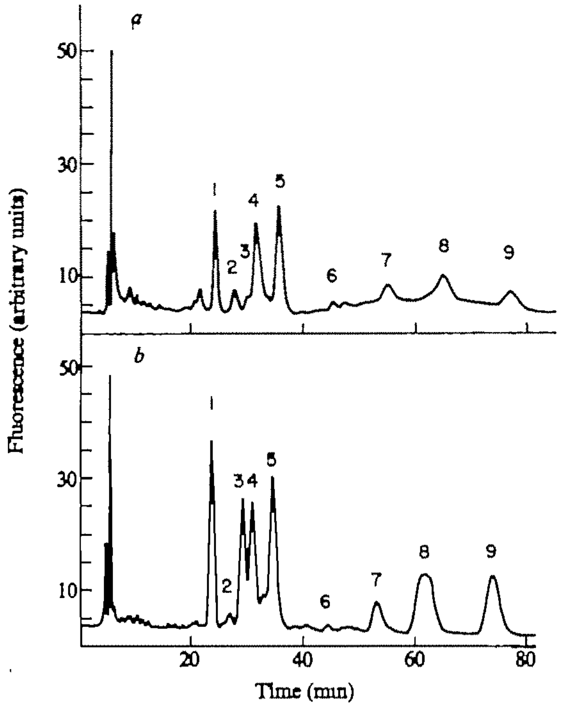

Fig. 2 Racemic (±) *anti*-BP diol epoxide was reacted with: *a*, double-stranded (replicative) ΦX174 DNA; *b*, single-stranded (viral) ΦX174 DNA. Adducts were formed and isolated as described in Fig. 1. The ratio of deoxyguanosine diastereomers derived from the (+) and (−) hydrocarbon is 20:1 for double-stranded DNA (the ratio of peaks 5 to 3, panel *a*), and 20:17 for the single-stranded polymer (the ratio of peaks 5 to 3, panel *b*). See text for discussion.

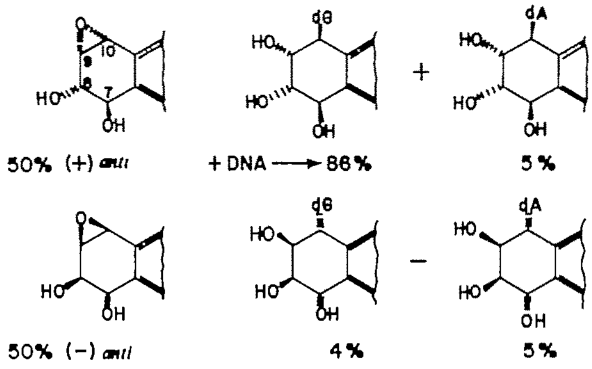

Fig. 3 The structure and per cent distribution of the principal guanine and adenine *trans*-addition products obtained by reacting racemic (±) *anti*-BP diol epoxide with native calf thymus DNA. The distribution also includes any *cis*-addition products (see text).

Figure 3 shows the structures of the *trans*-addition adducts and their per cent distribution obtained by reaction of racemic (±) *anti*-BP diol epoxide and native calf thymus DNA. (These percentages also represent any *cis*-addition products.) With the identification of adduct 9, we found that reaction of racemic (±) *anti* diol epoxide with DNA resulted in nearly equal distribution of deoxyadenosine diastereomer products, that is, adducts 7 and 9 from the (+) enantiomer of the hydrocarbon were about equal to adduct(s) 8 from the (−) enantiomer. By contrast, deoxyguanosine in DNA reacted stereoselectively with racemic *anti*-BP diol epoxide, that is, the ratio of adduct 5 derived from the (+) hydrocarbon to that of adduct 3 from the (−) enantiomer was 20:1. The same ratio of diastereomers was obtained by reaction of the optically resolved hydrocarbons and native calf thymus DNA (Fig. 1*b*, *c*). We initially postulated that the stereoselective binding could be a result of the hydrocarbons interacting asymmetrically with the secondary structure of DNA[14]. This postulate was tested by reacting racemic (±) *anti*-BP diol epoxide with double (Fig. 2*a*) and single (Fig. 2*b*) stranded ΦX174 DNA. The same distribution of stereoselective guanine adducts was obtained with native calf thymus DNA (Fig. 1*a*) and double-stranded ΦX174 DNA (Fig. 2*a*). Reaction of racemic (±) *anti*-BP diol epoxide with single-stranded ΦX174, however, resulted in nearly equal distribution of hydrocarbon-deoxyguanosine diastereomers (peaks 3 and 5). In addition, reaction with the single-stranded polydeoxynucleotide resulted in a significantly increased proportion of deoxyadenosine adducts. These same results were obtained with native and heat- or base-denatured calf thymus DNA. The ratio of deoxyguanosine diastereomers in the single-stranded calf thymus DNAs was approximately 1:1, and the proportion of deoxyadenosine adducts was 40% compared to 10% in the double-stranded polydeoxynucleotide.

These results demonstrated that the asymmetrical binding of the two enantiomeric *anti*-BP diol epoxides to the exocyclic amino group of guanine in double-stranded DNA was dependent on the secondary structure of the polymer. One possible mechanism for the ability of DNA secondary structure to distinguish two enantiomeric molecules is by stereoselective physical interactions (possibly intercalation) before covalent binding. Intercalation or some other physical interaction may readily occur with the (+) enantiomer but not with the mirror image hydrocarbon. Alternatively, the noncovalent interactions could 'fix' the hydrocarbon so that only one configuration is in a favourable position to react with the exocyclic amino group deoxyguanosine. The following observations suggest that intercalation or some physical association between the BP diol epoxide and DNA take place before covalent binding: (1) as with intercalation of BP[24] or actinomycin[25] into DNA, binding of the diol epoxide occurs with a preference for guanine sites, and (2) reaction with denatured DNA 'randomises' adduct formation (loss of stereoselectivity and more adenine binding). We propose such an intercalation model to account for the stereoselective interactions between BP diol epoxide and DNA. The lack of any stereoselectivity in the adenine covalent binding sites with either double- or single-stranded DNA suggests that the reaction mechanism may be different from that of guanine binding. In the case of adenine the hydrocarbon may react without any physical interactions modulating the ratio of diastereomers obtained.

A correlation between DNA binding and carcinogenic or mutagenic potency has been reported for several polycyclic aromatic hydrocarbons[3-5]. Wood *et al.*[26] have determined the difference in the mutagenic activities of the (+) and (−) *anti*-BP diol epoxides using a mammalian tissue culture cell line and two bacterial tester strains. The difference in mutagenic activity between the (+) and (−) *anti* diol epoxides in the mammalian cell line was of the same order as we found for the difference in the level of covalent binding of the two isomers to the N^2-guanine site in native DNA. Therefore, the extent to which these activated hydrocarbons react chemically with DNA *in vitro* correlates with their biological activities. These results suggest that, in addition to metabolic factors, chemical and physical interactions with DNA may be important in evaluating the biological potency of carcinogenic and aromatic hydrocarbons.

The regulation of gene expression usually involves protein–nucleic acid interactions[27]. As we have demonstrated highly selective binding between small organic molecules and DNA, the possibility exists that this type of interaction may also have a regulatory role in the normal functioning cell.

We thank Dr A. Burlingame for the high resolution mass spectra. This research was supported by the Biomedical and Environmental Research Division of the US Department of Energy.

Note added in proof: Of the four isomers, (+) and (−) *anti*- and (+) and (−) *syn*-BP diol epoxides, the (+) *anti*-configuration is the most carcinogenic in newborn mice[28]. Therefore, the extent of non-enzymatic, covalent binding of this enantiomer to double stranded DNA correlates not only with mutagenic activity[26] but also with tumorigenic potency.

Hydrolysis of protein in vacuoles isolated from higher plant tissue

THE vacuoles of higher plant cells are known to be sites o deposition of salts and metabolites. A role as the lyti compartment has also been proposed[1], and Matile has argue that the vacuole participates in the metabolism of higher plan cells in the same way that lysosomes do in other organism Recently, isolation methods have been developed which allow direct analysis of vacuolar constituents and we have show previously that the vacuoles isolated from the endosperm o young castor bean seedlings contain at least 25% of the cellula protein, 62% of the sucrose and various hydrolytic enzyme (acid protease, carboxypeptidase, phosphodiesterase, RNAase phytase and β-glucosidase) in amounts indicating a primaril (possibly exclusive) vacuolar localisation[2]. In this tissue it i known that when the dry seed imbibes water the outer, water soluble matrix of the protein bodies is dissolved and smal vacuoles containing the protein crystalloid are formed. Thes coalesce early in germination to form the large central vacuole and the remnants of the protein bodies disappear within a fev days as growth proceeds[3]. We have examined vacuoles isolate from the endosperm of 4-d-old seedlings, when it is known that net loss of protein is occurring. Here we compare the protei composition of the vacuoles with that of the origina protein bodies, and show that hydrolysis of th endogenous protein continues in the isolated vacuoles which ar free from other cellular components.

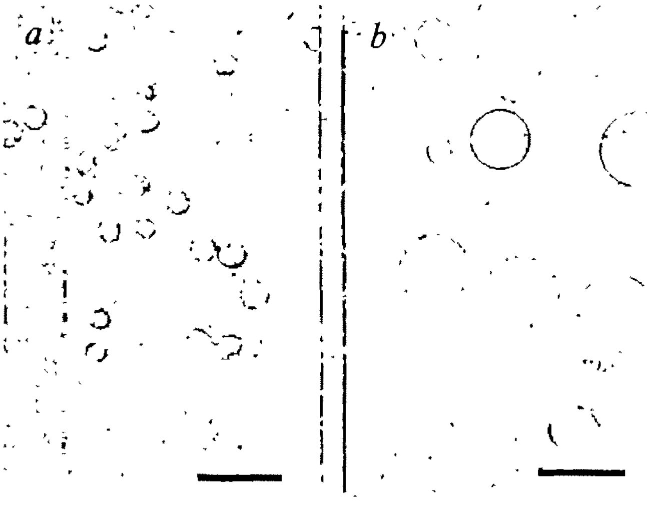

Fig. 1 Photomicrographs of *a*, protein bodies prepared from dry castor beans, and, *b*, vacuoles prepared from endosperm of 4-d-old seedlings and purified by passage into 40% sucrose containing 0.1 mM EDTA[2]. Bars, 50 μm.

Table 1 Protein content of protein bodies and vacuoles

	Protein bodies (mg per 10^6)	Vacuoles (mg per 10^6)
Total protein	0.71	1.92
Water soluble	0.14 (19.7)	0.90 (46.6)
Water insoluble	0.57 (80.3)	1.02 (53.4)

Isolated protein bodies and vacuoles (~1 mg protein in 100 μl) were mixed with 1 ml of water. After removing the insoluble protein by centriguation (10,000*g*, 10 min), the soluble protein was precipitated with 1 ml of 10% trichloroacetic acid, dissolved in NaOH and assayed by the Lowry procedure[7]. The insoluble protein was calculated by subtracting the amount of soluble protein from the amount of total protein determined on NaOH extracts of trichloroacetic acid precipitates of initial samples. Values in parentheses show percentages.

Seeds of castor bean (*Ricinus communis* cv. Hale) were soaked in running water for 1 d and germinated in moist vermiculite at 30 °C. Vacuoles were prepared as described previously[2], using 140 endosperm halves, removed from 4-d-old seedlings. The protein bodies were prepared from 20 dry seeds by the non-aqueous method of Yatsu and Jacks[4]. Figure 1*a*, *b* are photomicrographs of the isolated protein bodies and vacuoles, to the same scale. From analysis of total protein and from haemacytometer counts of appropriate samples, it was determined that the protein content of 10^6 protein bodies was 0.71 mg and that of 10^6 vacuoles 1.92 mg. Thus, at 4 d, each isolated vacuole still contains an amount of protein equivalent to several original protein bodies, as anticipated from the microscopic examination[3].

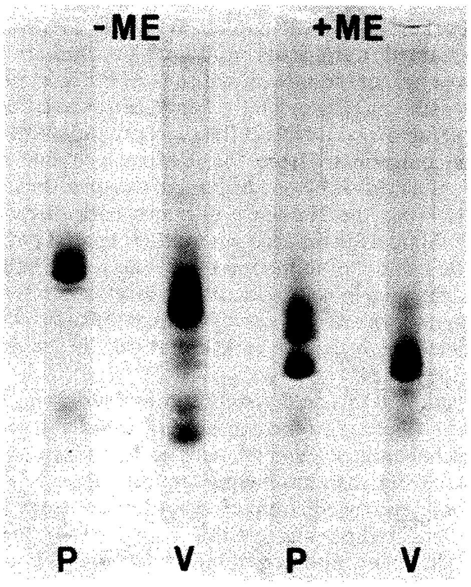

Fig. 2 SDS electrophoretograms of the protein bodies (P) and vacuoles (V) shown in Fig. 1. Samples containing approximately, 70 μg protein were subjected to SDS-polyacrylamide gel electrophoresis in the presence and absence of β-mercaptoethanol (ME) according to Tully and H.B.[5].

As shown in Table 1, only 20% of the total protein in protein bodies is water soluble, compared with 50% in the 4-d vacuoles. This indicates that digestion of the (water-insoluble) crystalloid protein is proceeding. Figure 2 shows typical SDS electrophoretograms of protein bodies and vacuoles. These were carried out as described by Tully and H.B. and approximate molecular weights of components estimated[5]. The whole protein body preparation yielded one major band (mw 60,000) and several minor bands, as previously shown[5]. In the vacuole preparation, the major band had disappeared and new protein bands, with lower mws (40,000, 30,000 and 18,000) were present. In the presence of β-mercaptoethanol, three major bands (mws 41,000, 35,000 and 30,000) were seen after electrophoresis of the whole protein body preparation, whereas two of these (mws 41,000 and 35,000) were not present in the vacuoles. These results show that larger protein components had been converted to smaller polypeptides, as expected from the action of hydrolytic enzymes known to be present in the vacuoles.

The vacuoles contain relatively high amounts of free amino acids (~90 nmol per mg protein). When intact vacuoles, as isolated in 40% sucrose, were incubated at 37 °C, the amount of free amino acid increased with time (Fig. 3*a*), showing that hydrolysis of endogenous protein was sustained in isolation.

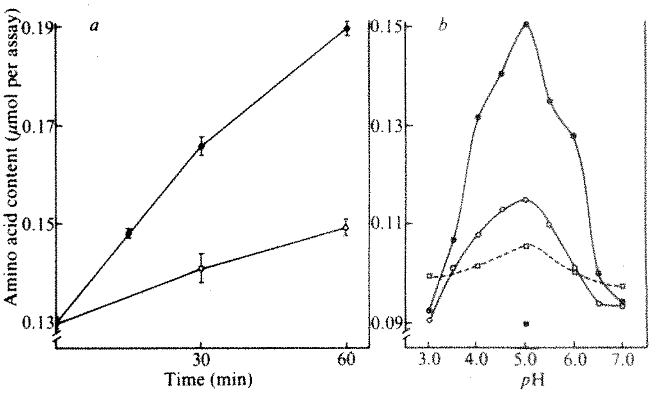

Fig. 3 *a*, Progress of amino acid accumulation is isolated vacuoles. For intact vacuoles (0), 40 μl of 50 mM citrate buffer, *p*H 5.0, in 40% sucrose was added to 10-μl samples of vacuolar preparation containing 156 μg protein. To obtain lysed vacuoles (●), 40 μl citrate buffer, *p*H 5.0, without sucrose was added to similar aliquots of vacuoles. Samples were incubated at 37 °C and the reaction terminated with 50 μl 10% trichloroacetic acid. After centrifugation the supernatant solutions were analysed for free amino acid using the ninhydrin method[6], with glycine as standard. *b*, Aliquots of a vacuolar preparation (105 μg protein) were treated as above to give intact and lysed vacuoles; the *p*H of the citrate buffer was varied as shown. Intact vacuoles were incubated for 30 min (□), and lysed vacuoles for 30 min (○) and 60 min (●) before amino acid analysis. A zero time control (■) is also shown.

Much higher autolytic activities were observed when the sucrose concentration of the medium was reduced by a four-fold increment of citrate buffer. As shown in Fig. 3*b*, the optimum *p*H for autolysis in both intact and lysed vacuoles was 5.0, although the response of the lysed vacuoles showed a much sharper peak.

Thus, the vacuoles show evidence that hydrolysis of endogenous protein has occurred within them before isolation and that this process is sustained in isolation. This seems to be the first direct demonstration of the proteolytic function of these organelles in higher plants.

Beech bark disease and archaeological crop marks

THE presence of 'crop marks' in aerial photographs is frequently used to detect archaeological features. These marks are produced by differences in plant size or colour which are related to the characteristics of the soil overlying or comprising the man-made feature. Pure stands of many arable crop species are known to show visible responses to soil heterogeneity. In the case of woody perennials we have found only one report describing the detection of archaeological structures by virtue of their influence on the growth of a crop[1]. This was the identification of ancient hut sites in Kenyan tea plantations where excess lime caused failure of the crop. We now report the detection of an ancient field system by virtue of its present-day relationship to patterns of a disorder in beech (*Fagus sylvatica* L.).

An aerial photograph of pure beech stands planted between 1920 and 1948 at Marden Forest, West Sussex, UK, shows some intriguing 'geometrical' patterns of chlorosis. In the area shown in Fig. 1 the trees were 25 yr old when the photograph was taken in 1973. A ground survey of this area revealed a series of scarps up to 1.4 m in height on gently sloping ground. The distribution of these scarps and their structure, as revealed by excavation of two of them, suggests that they are the remains of a field system of prehistoric or Romano-British origin. We have surveyed these scarps or lynchets, and Fig. 2 shows their relationship to the pattern of chlorosis plotted by photogrammetric techniques. Most of the affected trees seem to occur immediately below the scarps.

Our original purpose in examining the photograph had been to detect spatial patterns of beech bark disease which is present at this site and is caused by the scale insect *Cryptococcus fagi* Bär. and the fungus *Nectria coccinea* (Pers. ex Fr.) Fries. Like many plant diseases, beech bark disease has been surveyed using aerial photography[4], the symptom which makes such detection possible being foliar chlorosis[3]. This symptom may, however, be caused by other disorders; in particular, a nutritional deficiency in which beeches growing on thin calcareous soils are unable to absorb iron in adequate quantities[2].

The natural occurrence of nutrient imbalances in soil would not normally follow a spatial pattern of the type displayed by the chlorotic trees. At this site the soil is underlain by chalk and, in its undisturbed state, it probably included a shallow capping of slightly acid material. It is generally considered that in field systems of the type found here, gradual erosion over many years of ploughing along the contour has removed soil from the areas below the field boundaries. Apparently this process, together with disturbance of the underlying chalk, has produced a soil alkaline to the surface so that conditions conducive to nutritional chlorosis have arisen very locally and in a geometrical pattern.

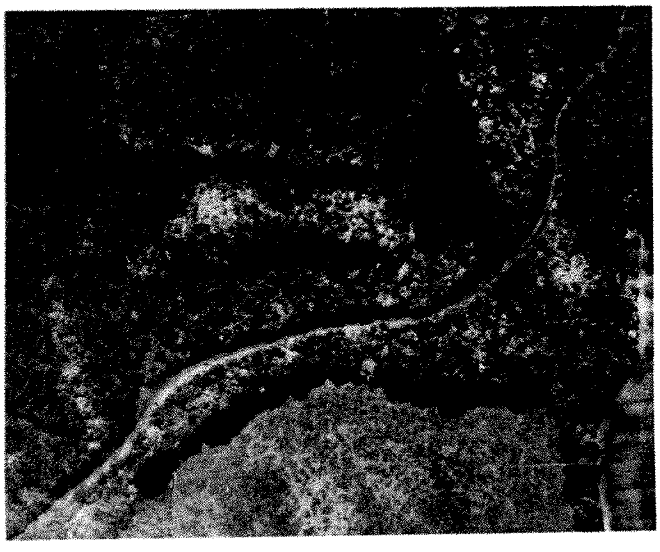

Fig. 1 Aerial photograph of geometrical patterns of foliar chlorosis at Marden Forest. (Crown copyright reserved.)

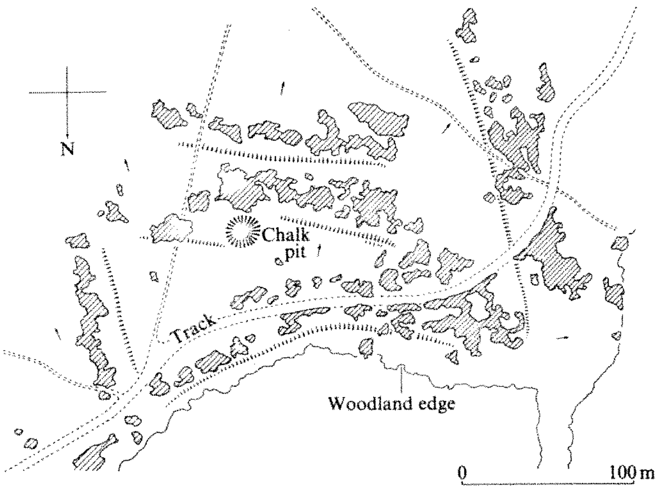

Fig. 2 Map of ancient field system and associated areas of foliar chlorosis. Hachures represent scarps (field boundaries). Cross-hatching represents chlorosis. The arrows indicate the direction of the down-slope.

Aerial detection of beech bark disease in areas where nutritional chlorosis is present would seem to be very difficult, although Parker[5] reported that, in the chalk downland plantations examined during his study of beech bark disease, chlorosis was not due to nutritional causes. Furthermore, there may be interactions between nutritional factors and beech bark disease. Soil factors could affect the susceptibility of the trees to the disease, quite apart from the confusion arising from the production of chlorosis by one or both of the disorders. It would be useful to study the incidence of beech bark disease and of nutritional chlorosis in an area where their spatial patterns are superimposed but can be mapped separately. We believe that the abrupt changes in soil type at the Sussex site offer such an opportunity and we are now surveying in detail the soil variation and the incidence of beech bark disease in the chlorotic and non-chlorotic zones.

The detection of this field system through observing chlorotic tree crowns suggests that the presence of woodland on a site of possible archaeological interest may be less of an obstacle to aerial survey work than has been generally supposed. As far as the detection and prediction of disorders in tree crops are concerned, our findings suggest that knowledge of the ways in which a soil has been modified by man's activities is important to the plant pathologist as well as to those who are responsible for establishing and managing plantations.

We thank Mr H. C. Bowen, of the Royal Commission on Historical Monuments, for discussions.

NATURE

We invite applications for 1979 Writing Fellowships and Sabbaticals at *Nature*.

Writing Fellowships

There will be opportunities for two or three scientists or journalists to travel on our behalf and write feature articles and news stories based on their experiences. We see these fellowships as a means of extending the coverage of our news pages.

Sabbaticals

We shall also have two or three vacancies for scientists with a particular interest in editing or writing to spend a short period working with the *Nature* staff.

For further details and application forms please write to:

The Editor, *Nature*,
4 Little Essex Street, London WC2R 3LF

stating which scheme you are interested in.

Low Temperature Biological Microscopy and Analysis

edited by PATRICK ECHLIN, an editor of the Journal of Microscopy

Low temperature techniques are now assuming a greater significance in biological investigations and the papers in this book cover both the nature of the freezing process in cells and tissues, and the complex physiochemical properties of ice as well as the application of low temperature methods to morphological and analytical studies. This is an extensive discussion of these techniques.

This book contains a selection of papers dealing with low temperature microscopy and microanalysis which have appeared in the Journal of Microscopy over the last 9 months. Many of the papers are from the Low Temperature Biological Microscopy meeting held in Cambridge in April 1977, organized by the Royal Microscopical Society. The others have appeared in the Journal of Microscopy and these papers are specifically concerned with low temperature techniques as applied to biological systems.

A History of Microtechnique

Brian Bracegirdle

This handsomely illustrated book is invaluable for an understanding of the process of microscopy. It provides a comprehensive reference for the historian of science and medicine, as well as the collector. More than 40,000 old microscope slides have been inspected and there are over 1,000 references. With the use of extensive text illustrations and photographs, this book sets down the main facts of the evolution and the development of histological methods.

Cloth DM 198,—; US $108.90
ISBN 3-540-08776-1

Prices are subject to change without notice

Plant movements cover a wide field of plant physiology. Volume 7 of the *Encyclopedia of Plant Physiology* reports the progress made on this subject since the appearance of Volume 17 of the first series of this encyclopedia (1959/62). This new volume is devoted particularly to the mechanisms of perception, transduction and response common to completely diverse types of movement. On the other hand, these steps of the reaction chain may be different even within a given type of movement for different examples. This volume clarifies and analyzes the signal chains that lead to movements in plants.

Contents:
General Aspects of Plant Movements. — Intracellular Movements. — Locomotion in Microbial Plants. — Movements Using Turgor Mechanisms. — Growth Movements.

A revaluation of all values

George Steiner

Science in a Free Society. By P. Feyerabend. Pp. 221. (New Left Books: London, 1978.) £7.50.

FORMALLY, this book is a mess. It is a patchwork of polemic, of autobiographical fragments, of re-iterations of or rapid addenda to an earlier book, *Against Method: Outline of an Anarchistic Theory of Knowledge* (New Left Books: London, 1978). In fact, it will make almost no sense to anyone who has not read Paul Feyerabend's main tract or who has not kept its principal arguments and areas of reference clearly in mind. The tone is, once again, truculent, self-serving, caustically dismissive of dissent and, at pivotal moments, rhetorical. A paragraph, chosen almost at random, will communicate the flavour and purpose (one can choose almost at random precisely because the technique of argument is one of circular incantation):

> "Of course, our well conditioned materialistic contemporaries are liable to burst with excitement over events such as the moonshots, the double helix, non-equilibrium thermodynamics. But let us look at the matter from a different point of view, and it becomes a ridiculous exercise in futility. It needed billions of dollars, thousands of well-trained assistants, years of hard work to enable some inarticulate and rather limited contemporaries to perform a few graceless hops in a place nobody in his right mind would think of visiting—a dried out, airless, hot stone. But mystics, using only their minds travelled across the celestial spheres to God himself whom they viewed in all his splendour receiving strength for continuing their lives and enlightenment for themselves and their fellow men. It is only the illiteracy of the general public and of their stern trainers, the intellectuals, and their amazing lack of imagination that makes them reject such comparisons without further ado."

The sleight-of-hand whereby moonshots, work on DNA and the mathematics and/or technology of non-equilibrium thermodynamics are conflated is no less representative of Professor Feyerabend's method than is the bullying lack of punctuation throughout the latter part of the passage.

As readers of *Against Method* will know, the author has two principal and related aims: to demystify the alleged rationality and methodological integrity of the 'exact' sciences and to remove these sciences from the prestigious, politically and socially determinant rôle which they play in current western society. To borrow Nietzsche's tag, Professor Feyerabend is arguing for 'a revaluation of all values':

Paul Feyerabend

Taken from the dust-jacket

> "Bringing a faint smile to the faces of people who have been hurt, disappointed, depressed, who are paralysed by some 'truth' or by the fear of death seems to me an achievement infinitely more important than the most sublime intellectual discovery: Nestroy, George S. Kaufman, Aristophanes, on my scale of values range far above Kant, Einstein and their anaemic imitators."

Feyerabend's position might be defined as that of a 'therapeutic anarchist' (it is very close to that of an educational iconoclast such as Ilich, who figures in the text if not in the index). The enemy, among others, is Popper: Sir Karl is "a mere propagandist" whose teachings and following constitute "a tiny outhouse" (elegance of expression is not among Professor Feyerabend's weaknesses). But the fundamental enemy—and here Feyerabend's polemic is precisely on target—is "the rise of intellectualism in Ancient Greece", and the unfolding of this intellectualism in the methodologies of Descartes and Kant and in the scientific world-image of Newton and his modern inheritors. It is this 'intellectualism', this belief ('illusory, naïve, finally ludicrous, says Feyerabend) in 'objective truths' and in the disinterested passions of abstract, mathematically-grounded theorising, which have brought the west to its current state of confused inhumanity. Trapped in our naïve, wasteful 'scientism', we no longer even have access to the pluralistic possibilities inherent in the 'animism', in the 'mysticism', in the intuitive, mythologically articulate mentalities and wealth of humane insight in cultures, in modes of apprehension which we have ostracised as 'primitive' or 'irrational' (as if the actual proceedings which led to the Copernican revolution or to Einsteinian relativity were not, in their own way, 'primitive' and 'irrational').

The text is most rewarding where it tells of the personal and pedagogic road which led Paul Feyerabend to his current stance. Kierkegaard's anti-rationalism was an incitement. Dada and the expressionist send-ups immediately after World War I were important (Feyerabend is absolutely right when he notes that Dadaists went deeper than anyone else in identifying the creative and 'deconstructive' "miracle of language"). There were Austrian Marxism and the Vienna School, with its ultimately unfulfilled promise of a rigorous yet also accurately descriptive logic of the sciences. And, above all, perhaps, there was California, with its plethora of informalities, instant utopias, 'Orientalisms', 'counter-cultures' and liberating sunshine.

If Feyerabend often knocks down straw-men—who now refuses to argue the status of the exact sciences, what serious mind is not worried about the technocratic enormities in our environment and politics?—he also scores shrewd hits. He is acute on the innocent 'scientism' of the Vienna Circle; his critique of positivistic paradigms amends and deepens Kuhn. He is robustly anti-parochial, following Protagoras in the conviction that a pluralistic view of values and ideals is the only way of stepping beyond one's village towards the human community at large. Thus, Professor Feyerabend's plea for a new catholicity of understanding is often poignant and persuasive. It is also, now and again, great fun. That a more patient sensibility, that a style of inquiry less contemptuous of disagreement, would give to *Against Method* a more effective place in the present climate of discourse, are considerations which, one fears, Paul Feyerabend would regard as time-serving, silly or both. The dust-jacket photo of the faintly sneering author seems to declare as much. This is a pity, for the issues raised are of the first importance. □

George Steiner is Professor of English and Comparative Literature at the University of Geneva, Switzerland.

Correlation of morphology with chemical composition

Electron Probe Microanalysis in Biology. Edited by D. A. Erasmus. Pp. 248. (Chapman and Hall· London, 1978) £15.

OFFERING the capability of chemical analysis *in situ* at a subcellular level, electron-probe X-ray microanalysis is an exceptionally effective means for the correlation of morphology and chemical composition Although the importance of the technique in biology is now well established, there are few texts giving the newcomer all-around guidance in its biological use Indeed, aside from the volume under review, only the 1977 book by John Chandler comes to mind

The editor's introduction is followed by a capable exposition by J C Russ of physical fundamentals and limits of performance The next two chapters are by J. A Chandler ("The application of X-ray microanalysis in TEM to the study of ultrathin biological specimens—a review") and by A. J Morgan, T W Davies and D. A Erasmus ("Specimen preparation"). Although there is considerable overlap between these sections, Chandler's chapter features a very extensive coverage of the literature on biological applications, whereas Morgan *et al.*, provide a much fuller comparison of a variety of preparative procedures The chapter by T. C. Appleton ("The contribution of cryo-ultramicrotomy to X-ray microanalysis in biology"), is mainly a good up-to-date presentation of the difficult procedure of preparing ultrathin cryosections of quench-frozen material In the following chapter ("The application of X-ray microanalysis to histochemistry"), I. D. Bowen and T. A. Ryder give a critical review of precipitation techniques with particular attention to enzyme localisation The final section, "X-ray analysis applied to the study of renal tubular fluid samples" by H O Garland, J. A. Brown and I. W Henderson, describes the special techniques used for the quantitative analysis of tiny samples of fluid obtained by micropuncture and documents the effectiveness of the electron-probe method in this field

Two limitations of the text should be noted. Firstly, as the editor states, "The field is . enormous and in order to follow certain aspects in depth, the contents of this book have been restricted essentially to the analysis of specimens in the transmission electron microscope." Nevertheless, although the emphasis on transmission microscopy is plainly evident, much of the contents, especially with regard to specimen preparation, applies equally well to studies based on scanning electron microscopy, and indeed the published X-ray analyses of micropuncture specimens have generally been done with scanning-type instruments

Secondly, as an over-view, the text is very limited in the area of studies associated with cryotechniques, the quantitative analysis of diffusible elements, and the attempt to control radiation damage by means of low temperatures Although Appleton's chapter gives an excellent summary of procedures for preparing cryosections, major results from several laboratories on the quantitative analysis of diffusible elements in cryosections have been published too recently for inclusion

However, the analysis of diffusible elements in cryosections is a field still in its infancy, and in any case requires specialised facilities. For the biological electron microscopist whose EM column is fitted with X-ray microanalytical facilities, the book gives a good idea of what can be done relatively readily, and how to begin doing it

Selective controlled fusions of membranes

Cell Surface Reviews. Vol. 5· Membrane Fusion. Edited by G. Poste and G. L. Nicholson Pp. 862. (North-Holland New York and Oxford, 1978.) $120

SELECTIVE, controlled fusions of membranes have long been recognised as major features of cellular and subcellular interactions in living organisms but only in recent years has any concerted effort been made to establish their significance and to identify the molecular events involved. A comprehensive treatment both of the phenomena and of attempts to account for them at the molecular level is thus both opportune and welcome.

Poste and Nicolson have made excellent choices of topics and authors to provide this comprehensive coverage, and the individual authors (with one or two exceptions) have poured all they had into it The result is a rather large book that takes a long time to read, but the articles and their extensive reference lists (with titles) provide a reservoir of information which those directly involved in fusion studies will explore with relish and at which those with more limited interests will nibble with profit.

Most of the book is inevitably taken up with descriptions of the circumstances and conditions in which membrane fusion takes place both *in vivo* and *in vitro* Fusion events involved in fertilisation in invertebrates (chapter 1) and in vertebrates (chapter 2) are discussed in largely phenomenological terms. Somatic and sexual fusions in myxomycetes and in fungi (chapter 5) are more amenable to studies of control factors, as also are myoblast fusion (chapter 3) and macrophage fusion (chapter 4) The latter can be studied in culture conditions as well as *in vivo.* Plant cell protoplasts also provide a useful system for the study of the conditions required for cell fusion (chapter 8) now that effective means of removing cell walls have been devised. Fusion events which transfer both vesicle-enclosed material and membrane itself through the intracellular system during endocytosis and/or exocytosis are also extensively covered (chapters 9–12).

Detailed descriptions of chemically induced (chapter 6), virus-induced (chapter 7) and Ca^{2+}-induced (chapter 8) fusions *in vitro*, provide a basis for speculations concerning factors which may contribute to fusion processes *in vivo* Throughout the book there are repeated references to possible influences of the nature and distribution of lipid components, the nature and distribution of protein and glycoprotein components and levels of Ca^{2+} ions on a variety of fusion processes, and there is a final chapter on problems in the physical interpretation of membrane interactions and fusion.

Thus this volume provides an authoritative, detailed and up-to-date assessment of studies relating to membrane fusion which will contribute substantially both to our understanding of and experimental approach to the problem

J. B. Finean

J. B Finean is Reader in Molecular Biology at the University of Birmingham, UK

HIGHLIGHTS FOR FEBRUARY 1979

REAGENTS FOR ORGANIC SYNTHESIS, Vol. 7

Mary Fieser & the late Louis F. Fieser

The seventh and latest volume in this distinguished series covers the literature from January 1976 through December 1976. Includes further references to the multitude of reagents previously discussed in the series, as well as hundreds of reagents introduced for the first time. Each reagent is listed with its uses, source of supply, method of preparation, critical comments, and references.

approx. 504 pp. (1-02918-1) **April 1979** $32.50

IMINIUM SALTS IN ORGANIC CHEMISTRY, Part 2

Edited by **H. Böhme & H. G. Viehe**

Second part of a two-volume work describing practically all aspects of the tremendous potential of the iminium-functions in synthons of nature, industry, and research. Twenty-two contributors from Europe, Russia, the USA, and Japan have written 14 chapters in these two volumes, which together provide a nearly complete documentation and analysis of iminium salts. The great range of coverage provides an understanding of the subject for the beginning organic chemist, as well as for those working in interdisciplinary fields of science

Part 2: approx. 832 pp. (1-90693-X)
Jan. 1979 $68.50
Part 1. 631 pp. (1-90692-1) **1976** $51.95

THIAZOLE AND ITS DERIVATIVES
Chemistry of Heterocyclic Compounds Series, Vol. 34, Parts 1, 2, & 3

Edited by **Jacques Metzger**

These three volumes represent a survey of this field over the past century up until December 1976. Part 1 discusses the properties and reactions of thiazole, general synthetic methods for thiazole and thiazolium salts, alkyl, aryl, aralkyl, and related derivatives; and more. Part 2 stresses aminothiazoles and their derivatives and mercaptothiazoles, hydroxythiazoles, and their derivatives. Part 3 deals with mesoionic thiazoles, dyes derived from thiazolium salts, and selenazole and derivatives.

Part 1: approx. 608 pp. (1-03993-4)
Feb. 1979 $80.00
Part 2: approx. 576 pp. (1-04126-2)
March 1979 $80.00
Part 3: approx. 368 pp. (1-04127-0)
April 1979 $40.00 (tent.)

FERMENTATION AND ENZYME TECHNOLOGY

Daniel I. Wang, Charles L. Cooney, Arnold L. Demain, Peter Dunnill, Arthur E. Humphrey, & Malcolm D. Lilly

Covers the basic microbiological, biochemical, genetic, and engineering aspects of fermentation, while presenting advanced methods of fermentation and control.

approx. 384 pp. (1-91945-4) **Jan. 1979** $25.00

INORGANIC SYNTHESES, Vol. 19

Edited by **D.F. Shriver**

This volume provides detailed, tested synthetic procedures for inorganic and organometallic compounds of current research interest. Each synthesis has been checked independently in a laboratory. Includes chapters on metal atom syntheses, organometallics, electrically conducting solids, main group compounds, and coordination compounds.

approx. 304 pp. (1-04542-X)
Jan. 1979 $25.00

Circle No. 08 on Reader Enquiry Card.

THE BIOSYNTHESIS OF AROMATIC COMPOUNDS

Ulrich Weiss & J. Michael Edwards

A comprehensive review of the chemical processes and substances involved in the formation of benzenoid rings by living organisms. Stresses the chemical nature of low molecular compounds that form the substrates of the biosynthetic processes.

approx. 624 pp. (1-92690-6) **Jan. 1979** $29.50

TECHNIQUES OF CHEMISTRY: Vol. 13, Laboratory Engineering and Manipulations, 3rd Ed.

Edited by **Edmond S. Perry & Arnold Weissberger**

A completely updated third edition of this volume from the important TECHNIQUES OF CHEMISTRY series, with four completely revised and rewritten chapters (I, II, III, and VI) and four new chapters (IV, V, VII, and VIII). **CONTENTS:** Selection of Materials for the Construction of Equipment. Laboratory Heat Transfer. Grinding, Blending, Screening, and Classifying. Pumps and Flow Measurement. Glove Box Technique. Mixing. Vacuum Technique. Solvent Removal, Evaporation, and Drying. Index.

approx. 544 pp. (1-03275-1) **Feb. 1979** $40.00

TECHNIQUES OF CHEMISTRY: Vol. 12, Separation and Purification, 3rd Ed.

Edited by **Edmond S. Perry & Arnold Weissberger**

"Separation and Purification" is part of the TECHNIQUES OF CHEMISTRY series that has become a world renowned treatise on modern chemistry technique. This new edition reflects the increase and greater importance of separation methods within the chemical sciences, resulting in a field now called Separation Science.

438 pp. (1-02655-7) **1978** $30.00

CONDENSED PYRAZINES
Chemistry of Heterocyclic Compounds Series, Vol. 35

G. W. H. Cheeseman & R. F. Cookson

Describes the preparation, properties, and uses of the more important bi- and tri-cyclic ring systems incorporating the pyrazine ring. Contains a survey of the developments in the chemistry of quinoxalines since the appearance in 1953 of a previous monograph in this series, and also provides the first authoritative reviews of the chemistry of such noteworthy related ring systems as the pyrrolopyrazines.

approx. 752 pp. (1-38204-3) **March 1979** $100.00

THE CHEMISTRY OF ANTITUMOR ANTIBIOTICS, Vol. 1

William A. Remers

The first book to deal with a number of antitumor antibiotics in a comprehensive way. Considers all aspects of their chemistry and biochemistry and much of their biology. Emphasizes the intellectual outlines of research in the subject. Illustrates discovery of these agents and their development into clinically useful anticancer drugs.

approx. 292 pp. (1-01791-4) **Feb. 1979** $29.00

BIOSTATISTICS IN PHARMACOLOGY, Volume 3

International Encyclopedia of Pharmacology and Therapeutics

Section 7 Volume 3

Editor: **A.L. Delaunois**, J.F. and C. Heymans Institute, Gent, Belgium.

The third and final volume of this series in the *International Encyclopedia of Pharmacology and Therapeutics* which deals with the application of statistics to medical science. This particular volume emphasizes computer techniques used in biostatistics for laboratory, field and industrial applications. The articles in this volume are designed to help the research worker obtain the maximum of information from the minimum of experiments. For easy reference, some tables which appeared in Volumes 1 & 2 are reprinted and inserted in a pocket in the inside back cover.

Transform techniques in chemistry

Transform Techniques in Chemistry Edited by P. R. Griffiths. Pp. 385. (Plenum: New York and London, 1978) $47.40.

MANY spectroscopists, particularly those using nuclear magnetic resonance, have had their field revolutionised in the past few years by the introduction of Fourier transform techniques but have been forced to pick up the new folklore in a haphazard manner for lack of a suitable general treatment of transform methods written from the point of view of the chemist. This excellent new book goes a long way towards satisfying this need It provides a convincing demonstration that the concept of Fourier transformation is common to a whole range of physical techniques, ranging from the well-known NMR spectroscopy and infra-red interferometry to the more recent Fourier transform ion cyclotron resonance Although Fourier transformation naturally dominates the discussion, it is shown that related techniques such as the Hadamard and Walsh transforms can also be useful to the spectroscopist in suitable circumstances.

This book is a collection of chapters by different authors, and can be divided into the mathematical and data handling topics (chapters 2–4, 7, and 11–13) and applications to specific types of spectroscopy or chemistry (chapters 1, 5, 6, 8–10 and 14). This method of compiling a book has the obvious strength of allowing the important sections to be written by the appropriate expert; in the present case there is an excellent description of Fourier transform ion cyclotron resonance by Comisarow. On the other hand, multiple authorship can mean undesirable repetition. Worse still, a given topic may be treated superficially several times over, no single author wishing to devote enough space for a definitive discussion. For example, the practice of 'zero-filling' interferograms raises some fairly fundamental questions that are seldom answered to the satisfaction of the average spectroscopist, and one would have expected the present volume to tackle this hot potato once and for all. Instead the subject is treated separately in chapters 4, 8 and 11, in each case rather uncritically.

This is an extremely useful book for locating those elusive but vital pieces of information the research worker always seems to be looking for; at the same time the general concepts are very well treated. Most readers will be surprised at the number of different areas where transform techniques are used and how related problems turn up in different forms in the different fields This broadening of our understanding could well lead to new experiments inspired by the methods used by our colleagues. Everyone will find something new in this book Even the jargon of our fellow spectroscopists can come as a surprise; the reviewer particularly noticed "dichotomizer", "cross-correlogram", "decimation" and "transgeneration".

In spite of the use of multiple authors, the material presented is remarkably up-to-date, and there seem to be no glaring omissions It would have been nice, however, to have seen some mention of Fourier transform methods of NMR imaging (zeugmatography) and the developing field of two-dimensional Fourier transformation.

Ray Freeman

Ray Freeman is Lecturer in the Physical Chemistry Laboratory at the University of Oxford, UK.

Soil profile recording

Soil Sampling and Soil Description By J. M. Hodgson. Pp 241 (Clarendon Oxford University Press Oxford, 1978.) £10.

FROM the outset it is essential to realise that this little book is not intended to be a field handbook Rather it is a review of 'how and why' specific profile features should be recorded together with a summary of the descriptive methods adopted by various national and international organisations

In the opening chapter the author considers the reasons for studying the soil in the field and the need to describe accurately profile features Chapters 2 and 3 provide a concise review of methods of profile site selection, description and preparation.

The 'how and why' of soil description is the central theme of chapter 4, which provides a comprehensive list of the soil features the field scientist is likely to encounter Unfortunately the approach adopted in this chapter is by no means uniform Each feature is dealt with in turn, in some instances the reasons for selecting a particular feature are discussed in detail, whereas in others the importance is assumed to be obvious Similarly when dealing with possible means of measuring or classifying a particular feature the methods are sometimes considered in detail, as for example in the case of structure or as in the case of roots only perfunctorily.

This long account is followed by two succinct chapters covering techniques of data recording and sample collection Of particular value is the section on recording of data in a form amenable to computer storage. (In this section figures 5 5 and 5.8 are transposed) The final chapter is in the form of a summary of the profile features used in soil description by some 28 different organisations The reviews are necessarily brief and details are only given where the procedure or feature used differs from those in the USDA 1951 Handbook. This chapter is valuable if only because it brings together for the first time the approaches adopted by a variety of agencies.

Overall one is left with the question of what is the purpose of this book? Had the chapters on the 'how and why' of soil description considered the question of 'why' in greater depth then this would indeed have been a useful text

M. J. Alexander

M. J Alexander is Lecturer in Geography at the University of Durham, UK.

Quantum chemistry

Quantum Chemistry. (Reference Edition.) By J. P. Lowe. Pp. 599. (Academic: New York, San Francisco and London, 1978.) $49.50; £32.15.

QUANTUM CHEMISTRY signifies different things to different minds. Some forget the 'chemistry' and provide for chemists simplified, or simply curtailed, versions of books on quantum mechanics. Some concentrate on molecular properties with and without spectroscopy; others concentrate on molecular structure. The last are increasingly based on computer techniques—as they should be—for they have provided the most important quantitative advances in recent years. In them lies the hope of simulating more precisely the processes that occur when molecules undergo the dramatic changes that result in reaction, and in them lies one of the very few tests we possess of the qualitative ideas that underlie our understanding of the equilibrium geometries of molecules as well as their reaction characteristics.

Dr Lowe has written a book that covers parts of this well trodden ground. It is aimed principally at readers whose interest is in molecular structure, and to say what is not in it may be as helpful as saying what is in it: thus it is not a spectroscopy book, nor is it a molecular properties book. It does, however, deal with basic quantum mechanics (but reserves operator properties until well on into the text), atomic structure, and then, for over half the book, molecular structure. The level of treatment of molecules is slightly beyond what undergraduates normally meet, and covers basic LCAO–MO theory, Hückel theory, and SCF–MO theory. The final chapter, which I suspect the author is proud of most, is on 'qualitative molecular orbital theory', which turns out to be the Walsh-type argument for structure and Woodward–Hoffmann rules for reactivity.

Although the basic material is treated in other books with similar titles, there are aspects of the treatment that make the book attractive. The author clearly has an eye for the interesting analogy and felicitous example, and readers will enjoy the sensitivity of his exposition. There are places where he apparently has not troubled to think up an explanation (for example, the Hund rules), but on the whole readers will find themselves in the presence of an imaginative and reliable interpreter.

At various points I thought the author's judgement faltered. For instance, I think very little purpose is served by working through in detail the old-fashioned way of solving the harmonic oscillator Schrödinger equation; and even less is served by sketching the hydrogen atom solution before talking about angular momentum, leaving angular momentum itself largely unexplained, and being unhelpful about spin. Hückel theory is old hat, but it was nice to see modern judgements (and comparison with experiments, as in hyperfine coupling constants) brought into the discussion. Various nice examples of perturbation theory are presented, and group theory is presented in a suitably pragmatic way.

In summary, Dr Lowe has written a nice book, which covers old ground in a pedagogically attractive and largely contemporary way. Readers will find it an agreeable, accessible commentary on modern structural quantum chemistry.

P. W. Atkins

P. W. Atkins is Lecturer in Physical Chemistry at the University of Oxford, UK.

Insect behaviour

Insect Behavior. By R. W. Matthews and J. R. Matthews. Pp. 507. (John Wiley: Chichester, UK; and New York, 1978.) £15.85.

IT is rare to find a major gap in the present plethora of scientific books but a treatise on insect behaviour has been badly needed for years. There is surely more published work on this subject than on the behaviour of any other animal group. A great part is descriptive and no small part anecdotal but insect behaviour has also been the subject of innumerable analytical studies, the special strength of which has been their leaning toward physiology rather than psychology.

This book makes a bold and within its purpose successful attempt to fill the gap. Faced with the superabundance of information and the infinite diversity of insect behaviour the authors had to choose between breadth and depth, and chose breadth. Comprehensiveness probably was in fact the most pressing requirement for a first book in the field, one that would serve as a detailed 'guidebook' for entomologists and behaviourists generally.

Inevitably it will be said that in trying to cover everything the authors succeed in saying little about anything. Again and again the reader is tantalised by the opening of an interesting topic only to find it closed again for another. However, while holding to their comprehensive purpose the authors have gone some way to meeting this criticism by frequently interpolating fuller 'case-studies', and by ending every small subsection with citation of up-to-date reviews and books on that specific theme, an invaluable feature. It is difficult to think of any topic that does not get some introductory treatment in the book: slave-making and Zeitgebers, cannibalism and coyness, heritability, flicker-fusion, the r–K spectrum, Solanum alkaloids, stimulus filtering, bioluminescence, parental investment . . . it is all there. The large Subject Index unfortunately does not adequately underpin the guidebook function, the bulk of it being insect names. Let us hope the authors will provide a fuller one in future editions.

The authors describe the general approach of their book as "ethological", meaning a primary concern with descriptions, functions, behavioural ecology and evolution. After an introductory chapter including a warning against anthromorphism and teleology, one chapter of 40 pages deals sketchily with nervous and hormonal mechanisms. The rest of the book is devoted to the gamut of behavioural activities under two main heads, "maintenance activities" of individuals, and "communicatory activities" between individuals of the same or different species. Maintenance is covered in chapters on "Spatial Adjustment" (locomotion, orientation, dispersal and migration) and "Feeding Behavior" (plant relations, food location, social feeding, food recognition and feeding regulation).

Communicatory activities take up the remaining 300 pages out of the total of 500, an emphasis reflecting the enormously increased recent academic and practical interest in these matters. Chemical, visual and mechanical (including acoustic) communication each have a chapter followed by three more strictly focussed on activity types, defensive and reproductive behaviour, brood care and social life. The arrangement is novel and effective. Illustrations are profuse, one on almost every other page, and include many photographs which have not all reproduced well. The reviewer has found one or two erroneous passages and it would be astonishing if there were not more in such an ambitious undertaking. There is naturally a certain transatlantic bias: it is strange, for example, not to find F Huber's work in an account of acoustic communication.

The book remains a monumental guidebook which insect and other behaviourists will want to have access to for years to come.

J. S. Kennedy

J. S. Kennedy is Senior Research Fellow and Emeritus Professor of Animal Behaviour at Imperial College of Science and Technology, University of London, UK.

Wiley NEW YORK · CHICHESTER BRISBANE · TORONTO

Sulfur in the Environment

by **J.O. Nriagu**, *Canadian Centre for Inland Waters.*

Part 1: The Atmospheric Cycle

A comprehensive interdisciplinary volume of articles, written by leading international experts, focusing on the chemical behaviour and biological effects of pollutant sulphur in the biosphere. It includes chapters on the sources, behaviour, and transport of atmospheric sulphur as well as on the costs and benefits of controlling sulphur emissions and the ambient air monitoring for pollutant sulphur compounds. *(Environmental Science and Technology Series)*

January 1979 — 478 pages
0471 02942 4 — $43.50/£23.00

Part 2: Ecological Impacts

This volume includes chapters on the biological, ecological, and health significance of sulphur pollution. *(Environmental Science and Technology Series)*

January 1979 — 494 pages
0471 04255 2 — $45.00/£24.00

Energy Utilization and Environmental Health: Methods for Prediction and Evaluation of Impact on Human Health

edited by **R.A. Wadden**, *University of Illinois School of Public Health.*

The contributors explain and demonstrate evaluation methods that can be used to incorporate public health considerations into the planning process of energy production facilities and pollution control strategies. The roles and interrelationship of sources, receptors, and the environment of basic data and methods to real problems in environmental planning is demonstrated. *(Environmental Science and Technology Series)*

December 1978 — 216 pages
0471 04185 8 — $31.65/£16.90

Principles of Ecotoxicology: SCOPE 12

by **G.C. Butler**, *Director, Division of Biological Sciences, National Research Council, Ottawa.*

For more than two years the programme of the Scientific Committee on Problems of the Environment (SCOPE), a committee of the International Council of Scientific Unions (ICSU), has included a project on Ecotoxicology. The objective of this project is to publish a book that will be useful to people dealing with the scientific aspects of pollution and to provide a suitable source-book for teaching graduate students the new science of Ecotoxicology. *(SCOPE Series)*

Contents: SECTION I: ENVIRONMENTAL BEHAVIOUR OF POLLUTANTS : General Considerations; Abiotic Processes; Biotic Processes; Models for Total Transport; Estimation of Doses and Integrated Doses; SECTION II: THE STATISTICAL ANALYSIS OF DOSE-EFFECT RELATIONSHIPS: The Statistical Analysis of Dose-Effect Relationships; SECTION III: EXPERIMENTAL TOXICOLOGY AND FIELD OBSERVATIONS RELATED TO ECOTOXICOLOGY: General Aspects of Toxicology; Terrestrial Animals; Aquatic Animals; Terrestrial Plants and Plant Communities; Ecotoxicology of Aquatic Plant Communities; Toxic Effect of Pollutants on Plankton; Toxic Effects of Pollutants on Microorganisms; Physical and Chemical Changes in the Environment with Indirect Biological Effects; SECTION IV: ECOSYSTEM RESPONSE TO POLLUTION: Ecosystem Response to Pollution: SECTION V: CONCLUSIONS: Conclusions.

December 1978 — 372 pages
0471 99638 6 — (paper only) $35.00/£14.00

Principles of Sedimentology

by **G.M. Friedman**, *Rensselaer Polytechnic Institute, Troy, New York,*
and **J.E. Sanders**, *Barnard College, New York.*

The field of sedimentology is surveyed comprehensively with a discussion of individual particles, physical, chemical and biological processes; depositional environments; stratigraphic units; and sedimentary tectonics. The wide coverage ranged from surface to subsurface, from submicroscopic to lithospheric plates. Problems and techniques for studying subsurface strata in relation to oil, gas, water, and mineral exploration are emphasised.

November 1978 — 808 pages
0471 75245 2 — $28.70/£15.70

Geological Evolution of North America 3rd Ed.

by **C.W. Stearn**, **R.L. Carroll**, and **T.H. Clark**,
all of *McGill University, Montreal.*

The authors use a regional approach to present the principles by which the earth's history is interpreted in terms of plate tectonics and describe the development of a single continent as opposed to a world overview. This edition has been completely rewritten and includes a full chapter on evolution. Satellite imagery has been used extensively for illustration.

January 1979 — 576 pages
0471 07252 4 — $22.50/£11.95

Hydrometry: Principles and Practices

edited by **R.W. Herschy**, *Department of the Environment, Water Data Unit, Reading.*

Streamflow data are required for the design of water supply systems, control of pollution, design of highway bridges and culverts, management of flood plains, forecast and management of floods, production of power, design and maintenance of navigation facilities, allocation of water for irrigation and industry, and for the development of recreation facilities. This book deals with methods of measuring flow in rivers and open channels to obtain the necessary data to serve the above functions.

December 1978 — 524 pages
0471 99649 1 — $53.00/£24.00

Weirs and Flumes for Flow Measurement

by **P. Ackers**, *Binnie & Partners, Consulting Engineers, London*
W.R. White, **J.A. Perkins** and **A.J.M. Harrison**,
Hydraulics Research Station, Wallingford, Berks.

This book covers both theoretical and practical aspects of water measurement using gauging structures. Its scope covers small discharges in laboratories and processing plants, as well as those larger discharges in rivers that remain amenable to measurement by this technique. The authors' policy has been to deal comprehensively with the most important flow-measuring structures for use in the field, the works and the hydraulic laboratory. The book gives sufficient theory for the user to understand the hydraulics of weirs and flumes but concentrates on the provision of practical information on the selection of the best type of structure the determination of suitable geometry and dimensions, the preparation of an accurate calibration, and methods of overcoming the practical and environmental problems, especially in river installation.

November 1978 — 348 pages
0471 99637 8 — $45.00/£19.50

Diagrams to show the variety of structure found in chemically transmitting synapses in the mammalian central nervous system — The Physiology of Excitable Cells

The Physiology of Excitable Cells
Second Edition

D. J. AIDLEY

The second edition of Dr. Aidley's widely acclaimed book retains the basic organisation of its predecessor, but incorporates many of the recent advances in our understanding of the physiology of excitable cells.

'Aidley succeeds brilliantly because he couples broad knowledge with an exceptional talent for clear exposition and with an interesting and even graceful style.' *Bioscience*

First Paperback Edition

Gauge Theories of Weak Interactions

J. C. TAYLOR

In recent years the study of weak interactions has been transformed by the development of gauge theories which display the unity of weak interactions with electromagnetism. The basic principles of gauge theories are explained, and the text will be accessible to anyone acquainted with the basics of quantum field theory and Feynman graphs.

Cambridge Monographs on Mathematical Physics 3

The Identification of Flowering Plant Families
Second Edition

P. H. DAVIS and J. CULLEN

This new, revised edition will enable the reader to identify all flowering plant families normally found either wild or in cultivation. The authors have included an illustrated discussion of floral structure and terminology and provided keys to 272 families with explanations of how to use them This book will be particularly appealing to students of botany and horticulture, amateur and professional botanists and keen gardeners.

Mechanical Behaviour of Ceramics

R. W. DAVIDGE

The science of the mechanical behaviour of engineering ceramics has now reached a stage where it is being used increasingly for engineering applications. This volume which brings together all the information previously scattered in numerous journals presents the scientific foundations of mechanical behaviour and demonstrates how these can be used in engineering situations. This is a useful text for students on materials-orientated courses and for research workers.

Cambridge Solid State Science Series **£15.00 net**

Electrical Properties of Polymers

A. R. BLYTHE

This book provides an introduction to the theory, experimental observations and use of electrical properties of polymeric materials. The subject is inherently interdisciplinary, being closely allied to the mechanical properties of polymers on the one hand and the semiconductive properties of inorganic substances on the other. This unique textbook which is the first to cover the whole field will be invaluable to students taking courses in polymer science and technology.

Cambridge Solid State Science Series **£17.50 net**

Arid-Land Ecosystems
Volume 1

Structure, Functioning and Management

D. W. GOODALL and R. A. PERRY

Man's use of arid lands is a sad record of deterioration of the natural resource base and a decline in the living standards of the people inhabiting these territories, a situation which can only be reversed if more is known about arid-land ecosystems. This volume and its companion provide a wealth of information on all aspects of desert areas, which will be of importance to university teachers and professional ecologists throughout the world.

International Biological Programme 16 **£37.50 net**

Case Studies in Genetics

M. A. TRIBE, I. TALLAN and M. R. ERAUT

This book provides an introduction to the fundamental concepts of genetics through a series of well researched case studies with special emphasis on human genetics. The book is designed for first-year undergraduates with a background in cell division, elementary genetics, protein synthesis and elementary probability theory. The book follows the self-instructional format of the others in the series, and includes an extensive array of self-assessment questions and an extensive glossary of terms.

newly on the market

Disposable transfer pipette. Variable Volumetrics. Variable Volumetrics introduce a disposable transfer pipette with ultra lean tube. This polyethylene transfer pipette has a tube so narrow that it will fit into almost any size test tube. It is a one-piece pipette complete with its own bulb, and will eliminate the danger of broken glass, operator contamination from having to change rubber bulbs and cross contamination of samples with contaminated pipettes or rubber bulbs. The pipette delivers 21–24 drops per ml, and has a maximum capacity of 3 ml.
Circle No. 52 on Reader Enquiry Card.

Fish-finding echosounders. Marconi Marine. The Chromascope K range of echosounders from Marconi Marine is designed to display received echoes from fish shoals and the seabed in colour on a television-type screen. Received echoes, fed from a storage memory circuit, are displayed in colours and tints which directly relate to the intensities of the signals received from individual objects. The result is a coloured mosaic of signals which integrate to form a chart-like presentation which shows fish shoals and the seabed in a manner which is easy to interpret. The integrated chart is constantly updated from the memory store.
Circle No. 53 on Reader Enquiry Card.

UV-vis spectrophotometer. Perkin-Elmer. In the model 552, UV-vis spectrometer from Perkin-Elmer, operation is both fast and simple. Concentration is automatically set by the keyboard and microcomputer. When a wavelength is keyed in, the monochromator rapidly sets itself at the press of a button. Both ordinate and abscissa data are clearly shown on large digital displays, and operating parameters such as mode, scan speed, format and response are conveniently displayed. The 552's automatic baseline compensation mode ensures baseline flatness of ± 0.001 A. An optional keyboard expander provides enhanced correction capacity and the ability to compensate over preselected wavelength intervals.
Circle No. 54 on Reader Enquiry Card.

Digital electronic thermometer. British Rototherm. British Rototherm have now introduced a compact electronic digital thermometer which combines accuracy, convenience and rugged reliability at a keen price. Designated the electrotherm, it resembles a conventional pocket calculator and is supplied complete with an easy-to-clean probe which can be stored in a built-in holder when not in use.
Circle No. 55 on Reader Enquiry Card.

Dewpoint meter. Shaw. The new Shaw automatic dewpoint meter uses room air moisture as a standard for rapid, automatic calibration to ensure that the sensor is fully responsive, without drift. The dewpoint meter requires only 4 to 5 minutes to reach equilibrium moisture readings even at very dry levels. The sensor is internally mounted within a desiccant chamber providing automatic dry-down between tests. This feature ensures that the meter is always ready to check dryness even down to 1 or 2 p.p.m. of water vapour. A direct-reading analog meter displays dewpoint, on a linear scale. Accuracy of reading is within ±1 p.p.m. or ±3 °C dewpoint, whichever is greater over the range from −80 to −25 °C dewpoint.
Circle No. 56 on Reader Enquiry Card.

Laboratory furniture. Sintacel. Metriscope from Sintacel is a comprehensive range of equipment capable of fulfilling the servicing and furnishing requirements of educational and laboratory accommodation. The range provides non-fixed furniture with overhead service booms and drainage equipment. All furniture is either movable or mobile and the working surfaces, with their flexible service/drainage connections, can be quickly re-arranged. The overhead service booms may provide such services as gas/electricity/water/vacuum/lighting. Drainage is normally dealt with by means of a regularly spaced grid of floor outlet points, but if so required, wall or overhead drainage may be provided.
Circle No. 57 on Reader Enquiry Card.

Laser systems. Coherent. Three new laser systems have been introduced by Coherent. The first of these, the CR-599-04 delay line dye laser, is a self-contained dye laser designed for synchronous pumping, and has an overall laser length of only 0.6 m. It is pumped by an actively mode locked ion laser, enabling optimal tuning range, stability and average output. The second system, the Series 467-SE, is a mode locking system consisting of an ultrastable RF oscillator/amplifier whose frequency is synthesised from a temperature-stable crystal oscillator reference, coupled to an acousto-optic modulator which mounts to any CR series ion laser. The third system, the CR-599-03E scanning dye laser, has an Etalon Servo lock to minimise mode hops, and has an operating range of 415–850 nm.
Circle No. 58 on Reader Enquiry Card.

Heating/stirring reaction module. Pierce. Pierce announces the introduction of their Reacti-therm heating/stirring module. The new dry block module is designed for use in the preparation of derivatives for GC and LC, for sample concentration, residue isolation and protein hydrolysis. A key feature of the unit is a continuously variable magnetic stirrer which is especially useful for dissolving sticky, hard-to-dissolve residues and for accelerating derivatisation reactions. The unit also has an ambient to 150 °C temperature range with ±0.5 °C control, a temperature stabilisation indicating light and a choice of interchangeable vial-holding aluminium blocks.
Circle No. 59 on Reader Enquiry Card.

Refrigerated constant temperature bath. Haake. The new heavy duty refrigerated constant temperature bath and circulator, model F3-K, from Haake, permits low temperature operation down to −30 °C. The unit has been specifically designed to control the temperature of laboratory objects where large amounts of heat must be removed. The refrigeration system offers a cooling capacity of 320 W at +20 °C (260 W at 0 °C). The integral temperature control unit provides continuous optimum control. Additional features of model F3-K include digital temperature setting, platinum resistance sensor (Pt100) and two safety devices for high temperature and minimum liquid level in the instrument's bath container.
Circle No. 60 on Reader Enquiry Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the cover.

GRAVITATIONAL-WAVE DETECTION AND EXPERIMENTAL GRAVITY—CALTECH

The California Institute of Technology is creating a new research group in gravitational wave detection and experimental gravity. Various investigations related to gravitational radiation are being planned, using laser interferometry, cryogenic electronics, or other techniques; and correlated experiments over a 7,600 kilometre baseline between California and Scotland may be performed. The group will be in a good position for close collaboration with Caltech's gravitation theory group, and also for pursuing gravity experiments in space in association with Caltech's Jet Propulsion Laboratory.

Inquiries are invited from outstanding experimental physicists, engineers, or technicians who might wish to join this new group. It is anticipated that the following types of appointments may be made in 1979 and 1980: research staff at levels equivalent to assistant, associate, or full professor but without teaching duties; assistant professorships; postdoctoral fellowships; and technicians. Inquiries from women and minorities are particularly encouraged.

Inquiries — including curriculum vitae, lists of publications, and letters of recommendations sent independently —should be sent to Professor Ronald W. P. Drever, 130-33 Caltech, Pasadena, California 91125, or Department of Natural Philosophy, Glasgow University Glasgow G12 8QQ, Scotland.
9411(A)

UNIVERSITY OF GLASGOW LECTURESHIP IN PHARMACOLOGY

Applications are invited from medically and/or scientifically qualified pharmacologists for a Lectureship in Pharmacology. The salary will be within the range £3,883 to £5,604 of the Lecturers' scale £3,883 to £7,754 (interim), with placement according to qualifications and experience.

Further particulars may be obtained from the Secretary of the University Court (Room 18), University of Glasgow, Glasgow C12 8QQ, with whom applications (eight copies), giving the names and addresses of three referees, should be lodged on or before February 16, 1979.

In reply please quote Ref. No. 4263/1M. 9414(A)

ST PATRICK'S COLLEGE
Maynooth
(Recognised College of the National University of Ireland)
LECTURER/JUNIOR LECTURER IN MATHEMATICAL PHYSICS

Prior to application, further details may be obtained from the Secretary, Academic Council, St Patrick's College, Maynooth, Co. Kildare, Ireland.

Salary Scales: Lecturer: £6,035 to £7,157; Junior Lecturer: £4,493 to £5,237. 9396(A)

Anglian Water Authority
ASSISTANT TEAM LEADER
(Mathematics)
Post Ref: H6R003 Grade 6
£5,133–£5,493 p.a.

Applications are invited for the above post currently based at the Great Ouse River Divisional offices, Cambridge. The successful applicant should preferably be a graduate in mathematics with experience in the water quality modelling of estuaries, coastal waters and reservoirs, and the organisation and collection of associated data. In addition to his individual projects, the successful applicant will also be expected to assist other team members in all aspects of their varied chemical and biological investigations, including computer programming, data processing and statistics.
The post carried a Regular User Car Allowance and N.J.C. conditions of service, including a contributary pension scheme, apply.

Please write, or telephone 0223 61561 ext. 259 for an application form (returnable by Friday 23rd February, 1979) to Mr. M. J. Pearson, Regional Research Team Leader:—

GREAT OUSE RIVER DIVISION,
Great Ouse House, Clarendon Road,
Cambridge, CB2 2BL 9413(A)

APPOINTMENTS VACANT

THE ROYAL VETERINARY COLLEGE
University of London
Division of Preclinical Studies
DEPARTMENT OF ANATOMY
LECTURER IN ANATOMY

Applications are invited for the above post which is available from October 1, 1979.

The Department has responsibility for teaching the topographical and systematic anatomy of the domesticated animals and provides a more general course in Histology and Embryology.

The person appointed will be expected eventually to undertake integrated teaching of these components but will have immediate responsibilities for the teaching of gross anatomy of large animals. The appointee will be encouraged to engage in research.

The post is based at Camden Town.

Salary Scale (under review): £4,333 to £8,204 including London Allowance. Initial salary determined by experience and qualifications. Superannuation under the Universities' scheme.

Removal expenses up to £800 may be reimbursed in approved circumstances.

Application form and further details from the Assistant Secretary (Personnel), The Royal Veterinary College, Royal College Street, London NW1 0TU. Telephone 01-387 2898.

CLOSING DATE FOR APPLICATIONS: March 5, 1979. 9419(A)

IMPERIAL COLLEGE
(University of London)
DEPARTMENT OF ZOOLOGY AND APPLIED ENTOMOLOGY

Applications are invited for two temporary Lectureships in the general field of Biomathematics, Applied Statistics and Systems Analysis. The persons appointed will be expected to contribute to the undergraduate and postgraduate teaching and to participate in the application of mathematical and statistical techniques in biological research. One of the posts will be related to the work of the Environmental Management Unit, which is concerned with the application of systems analysis, decision analysis and mathematical modelling to problems of Environmental Management A first degree in a mathematical, physical or biological subject is required, with relevant postgraduate experience.

Appointments will be made for two years at a point in the lecture scale (£3,883 to £7,754 plus London Weighting if appropriate: subject to review).

Applications in duplicate, with curriculum vitae and the names of two referees, should be addressed to the Head of Department, Department of Zoology, Imperial College, London SW7 2AZ, from whom further particulars may be obtained. Closing date for applications: March 1, 1979.
9417(A)

AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for appointment to the following:

Research School of Physical Sciences
SENIOR FELLOW/FELLOW/SENIOR RESEARCH FELLOW/RESEARCH FELLOW/POSTDOCTORAL FELLOW
DEPARTMENT OF SOLID STATE PHYSICS

The department, formed in 1971, currently has an academic staff of eight headed by Professor W. A. Runciman, and carries out research centred at present on spectroscopic studies of 3d, 4f and 5f transition metal ions in solids at low temperatures. Much of the completed experimental work has been carried out on 5f and 3d ions as well as colour centres in substituted oxides, synthetic and natural minerals. Theoretical studies in the Department have been aimed at providing detailed interpretations of spectroscopic parameters in terms of the underlying electronic processes. Several of the current experimental projects were designed explicitly to provide tests of these interpretations.

Applicants will be considered with previous research experience either in experimental spectroscopy (optical, Mossbauer or EPR) or in measurements of the structural or magnetic properties of metallic materials.

CLOSING DATE: **February 28, 1979.**

SALARIES:

Salary on appointment will be in accordance with qualifications and experience within the ranges: Senior Fellow $A23,737 to $A27,660 p.a.; Fellow $A17,694 to $A23,704 p.a.; Senior Research Fellow $A21,201 to $A25,289 p.a.; Research Fellow $A15,179 to $A19,813 p.a.; Postdoctoral Fellow $A15,179 to $A19,813 p.a. Current exchange rates $A1= $US1.14: £0.58.

TENURE:

Appointment as Senior Fellow/Fellow is five years in the first instance with the possibility, after review, of reappointment to retiring age 65 years; as Senior Research Fellow/Research Fellow normally for five years in the first instance with the possibility of extension to five years; as Postdoctoral Fellow for a maximum of two years.

OTHER CONDITIONS:

Reasonable appointment expenses are paid. Superannuation benefits are available for applicants who are eligible to contribute. Assistance with housing is provided for an appointee from outside Canberra.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should obtain further particulars from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF. 9400(A)

UNIVERSITY OF WOLLONGONG
Australia

LECTURER IN CHEMISTRY
(Limited Term)

Applications are invited for a ecturership in the fields of analytical and organic chemistry for duties associated with undergraduate and postgraduate courses The appointment will be made for a period not exceeding four years. Applicants should hold . Ph.D. degree or its equivalent and preferably have had some postdoctoral research experience in organic mass spectroscopy and/or trace nalysis The successful candidate will be expected to establish a research programme actively utilising the department's mass spectroscopy facility

Further information may be obtained from Professor B Halpern, Chairman, Department of Chemistry, in the University

Closing date **March 31, 1979.**

SENIOR LECTURER/ LECTURER IN COMPUTING SCIENCE (Tenurable)

Applicants should have a Ph D in Computing Science or equivalent qualifications together with demonstrable research ability and experience Preference may be given to applicants with experience in such areas as operating systems, computer aided learning or software tools

The Computing Science Laboratory ontains 16 terminals timesharing an nterdata 7/32 computer under UNIX The main computer is a UNIVAC 106 Both systems are available for teaching and research A Microomputer laboratory is under development

Further information may be obtained from Professor Juris Reinfelds, Chairman, Department of Computing Science, in the University

Closing date **March 1, 1979.**

Salary ranges Lecturer $A15,786 to A20,737, Senior Lecturer $A21,180 to A24,687, commencing salary according to qualifications and experience Fares to Australia (for appointees and dependants) and a relocation allowance are paid For a limited term appointment a contribution towards repatriation fares on conclusion of appointment may be made

Further particulars and application rocedure obtainable from the Association of Commonwealth Universities Appts.), 36 Gordon Square, London VC1H 0PF 9420(A)

UNIVERSITY OF SOUTHAMPTON

POSTDOCTORAL RESEARCH FELLOW

DEPARTMENT OF BIOLOGY

Applications are invited from biologists with interests in Taxonomy to work with Dr F. A Bisby and Dr J White for three years commencing March/May 1979 The S R C unded project will involve building a data-base with morphological and chemical legume data and experimenting with the provision of novel taxonomic services for evaluation by a users' panel The successful applicant will have an interest in the use of computer-based techniques in taxonomic problems

Starting salary from £3,883 to 4,382 plus U S S benefits

Further particulars may be obtained from Mrs E C P Sears, Staffing Section, The University, Highfield, outhampton SO9 5NH to whom applications with curriculum vitae and names of two referees should be sent as soon as possible, and not later than March 2, 1979 Please quote reference number 1707/R/Na. 9401(A)

unilever research

Scientists – Animal Feedstuffs

Due to reorganisation we have the following four vacancies in our Raw Materials and Animal Production Section:

Monogastric Nutritionist (Ref: CH-233M)
The job holder will plan and direct the work programme of a small research team carrying out studies on monogastric metabolism/nutrition with the objective of further understanding the relationships between diet and animal performance. This will include the development of experimental techniques for studying protein metabolism in monogastrics and computer simulation in animal growth.

Candidates should have an honours degree in biochemistry/nutrition with research experience to Ph.D. or similar level in pig or poultry nutrition. Experience in computing would be advantageous.

Ruminant Nutritionist (Ref: CH-234M)
The job holder will plan and direct the work programme of a small research team carrying out studies on ruminant metabolism with the objective of improving utilization of raw materials in feedstuffs.

Candidates should have an honours degree in agricultural science/nutrition with research experience to Ph.D. or similar level in animal nutrition with particular emphasis on ruminants.

Raw Materials Biochemist – Animal Feedstuffs
(Ref: CH-235M)
The general area of work is raw materials in support of Unilever's animal feedstuffs business. The work involves evaluation of raw materials and development of methods for improving their nutritive value for use in animal feeds, mainly for ruminants.

Candidates should have an honours degree in biochemistry with research experience to Ph.D. or similar level in plant science, preferably with particular emphasis on protein, carbohydrate or lipid structure and metabolism. An appreciation of farm animal nutrition and experimentation would be useful but not essential.

Nutritional Biochemist – Animal Feedstuffs
(Ref: CH-493A)
The general area of work is the exploitation of fats in animal feedstuffs. The research programme covers two main aspects:

(a) The evaluation of fats as energy sources for pigs, poultry and ruminants.
(b) The effects of fats in diets on primary and secondary production characteristics (e.g. carcass composition) of farm species, and their interaction with other dietary components.

Candidates should have a good honours degree or M.Sc. in biochemistry with chemistry and preferably with some experience or knowledge of lipid biochemistry/metabolism.

A good starting salary dependent on qualifications and experience and other Unilever benefits of employment will be offered to the successful candidate.

Please write for an application form and quoting reference number to:

Miss J. Kenny,
Recruitment and Career
Development Manager,
Unilever Research,
Colworth Laboratory,
Unilever UK Central Resources Ltd.,
Colworth House, Sharnbrook,
Bedford MK44 1LQ.

9402(A)

Universiteit van Amsterdam

Applications are invited for a teaching and research post

lecturer (m/f)

(wetenschappelijk medewerk(st)er)

in the Department of Structural Geology.

Duties will include field and laboratory courses in theory and practice of analytic structural geology, and research.
Applicants should have experience in small scale tectonics. Experience of work on the relationship deformation/metamorphism will be an asset.
Salary in accordance with background and experience.

Applications, with curriculum vitae, precise research interests and the names of at least two referees, should be sent to:
Prof. Dr. C. G. Egeler, Geologisch Instituut,
Nieuwe Prinsengracht 130,
1018 VZ Amsterdam, the Netherlands
(quoting number 3013).

9403(A)

CENTRAL PUBLIC HEALTH LABORATORY

National Collection of Type Cultures (N.C.T.C.)

SYSTEMS DESIGNER/ PROGRAMMER

A systems designer/programmer, preferably a science graduate, is required for the operation of a bacterial identification service Bacteria from clinical sources are identified by probablistic analysis of test results by reference to computer-stored data bases Systems use Optical Mark Reader forms, Data Recognition (Dataterm 3) Machine, Extel punch tape terminal connected to the LUCS 6500 time sharing system, current software in FORTRAN IV There is considerable scope for improving the responsivness of the system and the efficient storage and retrieval of data, and to revise the methodology or explore alternative methods Sympathetic consideration would be given for specialised training, if required

Grading dependant upon basic qualifications in appropriate subjects and on experience

Salary scales Scientific Probationary scale £2,991 to £4,275 plus London Weighting (£354), Post Probationary scale £3,798 to £4,899 plus London Weighting or Senior Scientific scale, if applicable, £5,451 to £6,837 plus London Weighting N H S Designated scale 9 £4,959 to £6,025 plus London Weighting

Ring 01-205 7041 for a more detailed job description (Dr L R Hill, on Extn. 47) and for an application form (Personnel Officer, on Extn 12)—Central Public Health Laboratory, Colindale Avenue, Colindale, London, N W 9 Closing date February 15, 1979

9293(A)

UNIVERSITY MARINE BIOLOGICAL STATION MILLPORT

Isle of Cumbrae, KA28 0EG

Applications are invited for

TECHNICAL POSTS

in the Grades UTS3 and UTS1

Further details and applicati forms may be obtained from th Station Secretary at the above addre to whom completed forms should returned not later than February 1979

9456(A)

MEDICAL RESEARCH COUNCIL

Radiobiology Unit,
Harwell, Oxon

A vacancy has arisen for a

RESEARCH OFFICER/ TECHNICIAN

to work on studies of damage to DNA by ionising radiation Experience in either microbiology or electron-microscopy of macromolecules would be an advantage Enthusiasm and adaptability are essential

Qualifications for Technician are H N C. or equivalent while a Research Officer would have at least two years relevant experience in addition

Salary scales are £3,261 to £4,680 for Technician and £3,582 to £4,902 for Research Officer. Assisted transport and modern hostel accommodation for single people are available

Applications, giving full personal details including the names of two referees, should be addressed to The Administrator, M.R C Radiobiology Unit, Harwell, Didcot, Oxon OX11 0RD Ref KB2

9459(A)

UNIVERSITY OF BRISTOL

DEPARTMENT OF GEOLOGY

ROCK-SECTION TECHNICIAN WANTED

Applications are invited for a person to take charge of the rock-cutting workshop The appointed person will have had several years experience in this type of work together with some educational qualifications

The position carries a salary of £3,186 to £3,720 per annum (Grade 5) (scale under review).

Applications, including the names of two referees, to The Superintendent, Department of Geology, Queens Building, University Walk, Bristol BS8 1TR To be received within two weeks of this advertisement appearing

9449(A)

UNIVERSITY OF READING

DEPARTMENT OF PHYSIOLOGY AND BIOCHEMISTRY

RESEARCH ASSISTANT

required as soon as possible for an S R C funded research project on the neuroendocrine control of ovulation in birds The appointment will be for a fixed period of up to two years depending upon the starting date Applicants should be graduates in physiology, pharmacology or zoology and should have a good background in neurophysiology An interest in neuroendocrinology would be an advantage Starting salary up to £3,634 per annum (under review) U S S superannuation Apply, quoting Ref MN 13A, with the names of two referees to Assistant Bursar (Personnel), University of Reading, Whiteknights, Reading RG6 2AH

9407(A)

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR

Applications are invited for the post of LECTURER IN MATHEMATICS Applicants should have research experience and publications in Pure Mathematics, preferably in an area of TOPOLOGY

The appointment, to commence on October 1, 1979, will be to the Universities' Lecturer scale —£3,883 to £7,754 per annum

Applications (two copies), giving details of qualifications and experience, together with the names and addresses of three referees, should be sent to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DG, from whom further particulars may be obtained

Closing date for applications February 28, 1979

9412(A)

We wish to appoint someone with experience in the medical or biological sciences to head a fully established research team in our Preclinical Research Department. The work of this team is mainly concerned with gerontological and pharmacological problems.

The person appointed will have a university degree in the medical or biological sciences backed by practical experience in the fields of anatomy, pathology or brain research Importance is also attached to a knowledge of morphometry and/or stereology and to a good command of the English language.

Applicants are asked to send a short letter of application in the first instance to:

SANDOZ

Sandoz Ltd., Personnel Dept. Ref. 1200,
Postbox, 4002 Basle, Switzerland.

9321(A)

THE MEDICAL COLLEGE OF ST BARTHOLOMEW'S HOSPITAL

(University of London)

West Smithfield, London EC1A 7BE

LECTURER POSTS IN PATHOLOGY WITH AN INTEREST IN TOXICOLOGY

Applications are invited for two posts as Lecturers in Pathology, tenable for a period of three years in the first instance The posts are suitable for those seeking their M R C Path and who are likely to develop an interest in toxicology with a particular emphasis on comparative histopathology.

The first two years would be spent mainly in following the normal training schedule rotating through two or hree of the four pathology disciplines at St Bartholomew's Hospital under he supervision as appropriate of the Professors of Histopathology, Chemical Pathology, Haematology and Medical Microbiology, and partly in being introduced to the toxicology work of he Department of Health and Social Security.

After completion of the Primary examination there will be opportunities for specialisation in comparative histopathology and toxicology under the supervision of the Director of D.H S S Toxicology Laboratory at St. Bartholomew's and in the Medical College of St. Bartholomew's Hospital A further fixed term contract of two years would be offered for this purpose Candidates completing the membership examination of the Royal College of Pathologists would, in addition to opportunities in Universities, Industry and the National Health Service, be eligible to apply or specialised posts in the Medical Divisions of D H S S in the field of oxicology The promotion prospects n D H.S S are good and there would be opportunities for research, special tudy and attendance at meetings

Salary for these posts will be on the cale £4,986 to £7,393 per anum plus '354 London Allowance.

Application forms and further information may be obtained from the Dean's Office of the Medical College t the above address, and should be returned to the Dean not later than February 28, 1979 9390(A)

QUEEN ELIZABETH COLLEGE

Kensington

(University of London)

PART-TIME LECTURER

DEPARTMENT OF MATHEMATICS required in session 1979–80 only, to teach a course of operational research to third year mathematics students. Forty lectures plus some tutorials, marking and examining Fee £800

Apply to Professor W B Bonnor, Mathematics Department, Queen Elizabeth College, Campden Hill Road, London W8 7AH 9442(A)

CHELSEA COLLEGE

University of London

GRADE 2B TECHNICIAN

Required to assist in research and teaching activities within the Biophysics Section of the Basic Medical Sciences Group Experience of Biophysical/Bioengineering or Physiological techniques would be an advantage.

Salary scale (under review) £2,994 to 3,345, inclusive of London Allowance.

Enquiries and application forms om the Secretary, Biophysics Laboratory, Chelsea College, 17A Onslow Gardens, London SW7 3AL (01-589 98). 9452(A)

SOUTH AFRICA

Veterinary Science Officers

Onderstepoort

The Department of Agricultural Technical Services at Onderstepoort in South Africa, wishes to appoint additional scientific staff for the establishment of the new Foot and Mouth Disease Laboratory which will be provided with all modern facilities for research and vaccine production.

Positions are available at several levels of seniority and applicants should hold the following minimum qualifications:

State Veterinarians	BVSc (or equivalent) degree
Chief Professional Officer (Veterinary)	BSc. (Agric.) Honours (or equivalent degree)
Chief Technician (Veterinary)	Diploma in Veterinary Technology or Diploma in Microbiology

Applicants must show initiative in undertaking research work and have experience in any of the following fields:

Virology; Immunology; Vaccine production and testing; use of fermenters for the production of cells in suspension.

Experience in Foot and Mouth Disease laboratories will be a recommendation.

Commencing salary will depend on qualifications and experience and appointments will initially be under agreement for a minimum period of three years (which can be extended to five years, after which the employee will be repatriated if desired).

Among the benefits offered are free passage to South Africa, removal of a limited amount of household effects and a "settling-in" allowance.

For further information contact Johan Cloete, Civil Service Officer, South African Embassy, Trafalgar Square, London WC2N 5DP.

Tel: 839 2211 ext 141/142. 9372(A)

UNIVERSITY OF OXFORD

E. P. ABRAHAM PROFESSORSHIP OF CHEMICAL PATHOLOGY

The electors intend to proceed to an election to the E P. Abraham Professorship of Chemical Pathology with effect from October 1, 1980 The stipend of the professor is at present £10,828 per annum

Applications (nine copies), naming three referees but without testimonials, should be received not later than March 26, 1979, by the Registrar, University Offices, Wellington Square, Oxford OX1 2JD, from whom further particulars may be obtained 9446(A)

POSTDOCTORAL POSITION

Research on the molecular biology of insect development, hormonal control of mRNA synthesis and in vitro transcription. Experience in nucleic acid hybridizations desired. Send resume and names of three references to. Dr S Sridhara, Department of Biochemistry, University of Mississippi Medical Center, 2500 North State Street, Jackson, Ms 39216 The University of Mississippi Medical Center offers equal opportunity in education and employment, Male/Female. 9376(A)

SURFACE PHYSICIST/ CHEMIST

Fusion energy research on plasma-wall interaction phenomenon involving atomic hydrogen chemical sputtering and surface cleaning. Uhv and surface physics/chemistry experience appropriate Appoint at Research Associate or Senior Research Associate level. Appointment for three years initially Well-qualified scientist sought. Appropriate salary available Write: Professor P. C. Stangeby, University of Toronto, Institute for Aerospace Studies, 4925 Dufferin Street, Downsview, Ontario, M3H 5T6 (416) 667-7729 9379(A)

THE UNIVERSITY OF MANCHESTER

LECTURER IN GEOLOGY

Applications are invited for this post from persons with an interest in Economic Geology, with particular reference to Ore Deposits. Initial salary range £3,883 to £4.631 per annum. Particulars and application forms (returnable by February 22) from the Registrar, The University, Manchester M13 9PL. Quote ref. 12/79/N. 9381(A)

THE UNIVERSITY OF LANCASTER

Postgraduate Research Assistant—Environmental Radioactivity

A postgraduate

RESEARCH ASSISTANT

is required for a three-year research project on the transport of artificial radionuclides from the marine to the terrestial environment The research is supported by a grant from the Natural Environment Research Council to Dr S R. Aston, of the Department of Environmental Sciences Applicants should have a good honours degree in chemistry, physics or environmental sciences, and experience in radioactive work.

Salary will be on the scale £3,884 to £4,882.

Further details may be obtained (quoting reference L105A) from the Establishment Officer, University House, Lancaster LA1 4YW, to whom applications (five copies) should be sent not later than March 16, 1979 9366(A)

UNIVERSITY OF VICTORIA
TRIUMF
Physics Department
requires
Research Associates in Intermediate Energy Physics

Two Research Associate positions are available for research in Experimental Physics at the TRIUMF 500 MeV Cyclotron. The successful applicants will be engaged in the University of Victoria research program at the Cyclotron, which includes studies of pionic and muonic X rays, rare decay modes of the pion and muon, and nucleon-nucleon scattering.

These appointments will be made initially for one year and are renewable. Salary will depend on experience, with a minimum of $15,500 per annum.

Send curriculum vitae, list of publications, and names of three referees to: **Dr. L.P. Robertson, Department of Physics, University of Victoria, Victoria, B.C. V8W 2Y2.**

UNIVERSITY OF VICTORIA

9409(A)

THE UNIVERSITY OF LEEDS
DEPARTMENT OF BIOCHEMISTRY

Applications are invited for the post of LECTURER in the above Department. The person appointed will participate in teaching biochemistry to science and to medical students. The Department provides good facilities and opportunities for research. The appointment will date from October 1, 1979.

Salary on the scale for lecturers: £3,883 to £7,754 (under review) according to age, qualifications and experience.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 83/71/D. Closing date for applications, March 12, 1979.

9367(A)

UNIVERSITY OF EDINBURGH
LECTURESHIP IN MICROBIOLOGY

Applications are invited for a newly established Lectureship in the Department of Microbiology. Applicants should have some experience or interest in applied microbiology, preferably in the area of agriculture or food.

Salary on scale £3,883 to £7,754 per annum, with superannuation benefits.

Further particulars may be obtained from the Secretary to the University, Old College, South Bridge, Edinburgh EH8 9YL, with whom applications by letter (five copies), including the names of three referees, should be lodged not later than February 28, 1979. Please quote Reference 1007.

9393(A)

AGRICULTURAL RESEARCH COUNCIL
Plant Physiologist

Applications are invited from Plant Physiologists who would like to join a small team of senior scientists who advise the Secretary of the Council on the scientific aspects of research administration.

The post is graded Senior Principal Scientific Officer with a **salary scale of £10,043 to £11,300 plus £465 for working in Central London.** Superannuation is under a non-contributory scheme analogous to that of the Civil Service.

Applications from candidates with a good honours degree of equivalent qualification and a successful record of research should be by letter accompanied by a full curriculum vitae and the names of two referees. Applications from candidates who applied previously will be automatically considered.

Further particulars from Miss M. J. Gard, Agricultural Research Council, 160 Great Portland Street, London W1N 6DT. Closing date March 9.

9351(A)

JUNIOR LABORATORY SCIENTIFIC OFFICER required for one year in the first instance for a research project on the biochemistry of muscular dystrophy supported by a grant from the Muscular Dystrophy Group of Great Britain. The work will involve measurement of enzyme activities and investigations of the properties of cell membranes. Some experience in handling animals is highly desirable. Salary in range £2,247 (age 18) to £2,904 or £2,370 to £3,015 according to age and qualifications, plus £354 London Weighting. Apply in writing, stating age and giving details of qualifications and experience (if any) to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, quoting Ref. B.C.

9406(A)

FACULTY POSITIONS OPEN
College of Agriculture and Food Sciences
KING FAISAL UNIVERSITY
Hoffuf, Saudi Arabia

Inquiries invited from qualified applicants at all academic levels to teach courses in the following fields:

Agricultural Economics
Animal Science
Animal Ecology
Agronomy
Agricultural Engineering
Dairy Science
Bee Keeping
Horticulture
Agricultural Extension
Water Resources and Climatology
Plant Pathology
Home Economics and Nutrition
Poultry Science

PREREQUISITES: Masters or equivalent degree; practical and/or teaching experience. Preference will be given to Arabic speakers.

Language of instruction is English.

Positions are available starting September 1979; interviews scheduled with the Dean in the United States and Great Britain during April/May 1979.

SALARY RANGES: Gross monthly salary in Saudi riyals. Approximate annual (sterling equivalent).

RANK:

Professor SR7,195 to SR9,595 (£12,983 to £17,314). Associate Professor SR6,435 to SR8,185 (£11,612 to £14,770). Assistant Professor SR5,245 to SR7,765 (£9,466 to £14,012). Lecturer SR3,280 to SR4,530 (£5,919 to £8,174).

BENEFITS

Free furnished accommodations; Substantial educational allowance for up to four children. Air fare to and from Saudi Arabia once a year for husband, wife and two children plus 60-day paid summer holiday. No Saudi income tax.

Send complete curriculum vitae stating preference of course and names, addresses and telephone numbers of three references to:

CSIRO AUSTRALIA

Research Scientist

(2 Positions)

Division of Mathematics and Statistics

Sydney or Melbourne

CSIRO has a broad charter for research into primary and secondary industry areas The Organization has approximately 7,000 employees—2,300 of whom are research and professional scientists—located in Divisions and Sections throughout Australia

General: The Organization's Division of Mathematics and Statistics has 104 staff, of whom over 70% are professional scientists, located at centres and laboratories in all capital cities and some major country towns

The Division's research in mathematics and statistics includes various aspects of fluid mechanics, statistical mechanics, optimisation, computational mathematics, distribution theory, multivariate analysis, stochastic processes, geostatistics, statistical inference and experimental design Application of this research to agricultural, biological, environmental, physical and industrial investigations currently includes the design and analysis of experiments and the modelling of ecological, physical, agricultural, and climatological systems Research is also being extended into industrial processes and mineral survey.

Professional scientists of the Division advise on the mathematical modelling and statistical analysis of investigations undertaken by other Divisions of CSIRO The Division now wishes to appoint to its Sydney and Melbourne groups, two experienced scientists at the Senior Research Scientist–Principal Research Scientist level

Location: Following an initial period of one to two months in Canberra, the two appointees will be located in Sydney and Melbourne respectively

Duties. To conduct methodological research in statistics and/or probability theory, and to advise scientists in other CSIRO Divisions on the planning of and interpretation of experiments and the use of mathematical and statistical methods The appointee would be expected to provide leadership for an appropriate sub-group within the Division of Mathematics and Statistics

Qualifications· A Ph.D. degree or equivalent qualification, with extensive research experience and an established international reputation in a relevant field Consulting experience would be an advantage

Salary: Appointment will be made within the salary range of Senior Research Scientist–Principal Research Scientist. $A19,572 to $A26,368 p a Senior scientists with appropriate research experience may be considered for appointment at a higher level

Tenure: Indefinite with Superannuation benefits

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 440/301, should reach —

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 28th FEBRUARY, 1979

Applications in U S A and Canada should be sent to —
The Counsellor Scientific, Embassy of Australia,
1601 Massachusetts Avenue, N W, Washington, D C, 20036,

CHAIR OF AGRICULTURAL BOTANY AT WYE COLLEGE

The Senate invites applications for the above Chair

Applications (10 copies) should be received by the Academic Registrar (N), University of London, Malet Street, London WC1E 7HU, from whom further particulars should first be obtained Closing date March 2.

A9416(A)

BRITISH ANTARCTIC SURVEY

The British Antarctic Survey have vacancies for Contract Staff on limited period appointments. All the posts involve visits to Antarctica for varying periods.

GEOLOGISTS (3 POSTS)

(ES 1/79) GEOLOGIST required to work in the Mineralogy, Petrology and Geochemistry Section of the Survey on plutonism of the Antarctic Peninsula. This project is a study of the plutonic rocks in certain areas of the Antarctic Peninsula over two summer field seasons. Some basic mapping will be required although many of the plutonic rock areas have already been studied. Geochemical sampling and subsequent analysis to determine magmatic and regional evolutionary trends will form a major part of the programme.

(ES 2/79) An experienced metamorphic petrologist/structural GEOLOGIST is required to work on the Pre-Middle Jurassic metamorphic complex of the Antarctic Peninsula. The successful candidate will undertake two Antarctic summer field seasons, the first being spent in Palmer Land examining areas previously mapped only in reconnaissance detail. During the second season the person will be working in a collaborative US/BAS study of the tectonic relationship between East and West Antarctica.

(ES 3/79) GEOLOGIST required to study the Jurassic palaeoecology and stratigraphy of the northern Antarctic Peninsula. The project will be primarily concerned with the plant-bearing sequences; field work is planned to document accurately these deposits with a view to assessing their significance The project will involve one summer field season.

Posts 1/79 and 3/79 to commence beginning of July, 1979.

Post 2/79 is available from May 1979 and must be taken up by early July.

Qualifications for all three posts· Minimum Upper Second Class Honours degree but preference will be given to applicants holding higher qualifications or relevant research experience especially for ES 2/79 and ES 3/79.

GLACIOLOGY SECTION (2 POSTS)

(ES 4/79) GLACIOLOGIST/OCEANOGRAPHER. A person is required to assist in the examination of conditions affecting the melting of ice at the bottom of ice shelves. Additionally, oceanographic measurements of current flow, salinity and temperature profiles, and the collection of seawater samples are undertaken.

Two visits to the Antarctic would be made within the first three years employment Qualifications should be a minimum of a 2(1) Honours Degree is physics, geophysics, oceanography, chemistry or engineering, and should include practical skills.

To commence beginning of July, 1979.

(ES 5/79) GLACIOLOGIST is required to assist in the development of radio echo equipment and the interpretation of results. Airborne surveys of ice thickness will be carried out in 1980/81; the person appointed would help gather data in the Antarctic and then reduce this data in Cambridge. The 1979/80 season will be spent carrying out related experiments, but based on the glacier surface, studying ice shelves and ice sheets to help understand their dynamic behaviour.

The person appointed should have qualifications in electronics with mathematical knowledge, or have a degree in applied maths or physics and a strong interest in electronics.

To commence beginning of July, 1979.

CHEMISTS (2 POSTS)

(LS 1/79) FRESHWATER CHEMIST to study the chemical relationships involved in nutrient cycling in maritime Antarctic lakes on Signy Island, South Orkney Islands. The proposed study is part of a comprehensive programme of limnological research Laboratory facilities at the Signy research station are good and there is a teleprinter link with headquarters and the Project Leader in the UK.

The individual selected will receive up to one year's training at the research laboratories, Cambridge and the Freshwater Biological Association, Windermere. Approximately 2½ years will be spent in Antarctica and one year will be spent writing up the work in Cambridge.

Applicants should have at least a First or Upper Second Class Honours degree. SCUBA diving experience is desirable but not essential as professional training will be given. Post available from July 1979 and must be taken up by September.

(ES 6/79) A CHEMIST is required to join a small team analysing trace impurities trapped in Antarctic snow. The aim is to determine changes in airborne pollution reaching the polar ice cap during historical time and to interpret palaeoclimatic variations from microchemical evidence contained in ice cores.

Following a year spent in the laboratory the successful applicant will undertake a summer field season in the Antarctic Peninsula collecting samples and carrying out some in situ analyses, which will involve an absence from the UK of about six months.

In the first instance the appointment is for a period of four years commencing June/July 1979.

Minimum qualifications are 2nd Class Honours Degree in Chemistry or Joint Honours Degree.

ATMOSPHERIC SCIENCES DIVISION

(AS 1/79) PHYSICIST/METEOROLOGISTS (6 Posts) and (AS 3/79) METEOROLOGISTS (2 Posts) to work at the Survey's observatories in Antarctica. Posts (AS 1/79) carry special responsibility for either ozone and radiation measurements, or geomagnetic and seismological programmes.

Successful candidates will be part of a combined meteorology/observatory physics team which is responsible for surface and upper air meteorology, observations of sea ice movement and snow accumulation.

Applicants should have a degree in physics or meteorology, or relevant HND or HNC qualifications. Preference will be given to candidates with practical electronic experience.

(AS 2/79) PHYSICISTS/ELECTRONIC ENGINEERS (2 Posts) to carry out studies of the ionosphere in Antarctica The basic work consists of operating and maintaining a variety of ionospheric remote sending experiments and interpreting the results. Applicants should have a background in either electronics with an interest in atmospheric sciences or in physics with electronic experience They should be prepared to work without supervision and be capable of improvisation in adverse situations

Successful applicants will commence training in July prior to sailing to Antarctica in October and must be prepared to spend 30-33 months continuous service overseas.

BRITISH ANTARCTIC SURVEY

BIOLOGICAL OPPORTUNITIES (6 POSTS)

Offshore Biological Programme

The British Antarctic Survey is engaged in a major offshore biological programme in the waters of the Southern Ocean around South Georgia.
About 3 months of each year will be spent at sea in active sampling.

(LS 5/79 a) KRILL PHYSIOLOGIST

The zooplankton team of the Offshore Biological Programme requires a physiologist to study the energetics of Antarctic Krill (*Euphausia superba*).

The successful applicant will be expected to undertake a research programme involving a significant amount of field work centred at the Survey's base on South Georgia and making use of the laboratory and aquarium facilities there.
Qualifications: PhD or minimum Upper Second Class with strong bias towards marine invertebrate physiology.

Appointment from 1 June 1979.

(LS 5/79 b) FISH PHYSIOLOGIST

A fish physiologist is required to work on the growth and development of an Antarctic group of fish (the Nototheniidae).

Most of the field work, which will probably extend over three Antarctic seasons, will be done at the Survey's base at Signy Island On returning to the UK, up to two years will be available for writing up the work.

Qualifications: PhD or minimum Upper Second Class, preferably with emphasis in fish physiology. SCUBA diving experience is desirable but not essential, as training will be given in this country.

Appointment from 1 June 1979.

(LS 5/79 c) ASSISTANT BIOLOGIST FOR ZOOPLANKTON TEAM

The Zooplankton Team of the Offshore Biological Programme requires a biological assistant to help with the sampling, sorting, identification and curation of zooplankton samples

The successful applicant will be expected to participate in the field sampling programme around South Georgia and in the Scotia Sea as well as in sorting and identifying the samples at the Institute Headquarters in Cambridge

Qualifications: 2 'A' levels or Pass degree, with zoology as main subject. Some experience of working at sea an advantage.

Appointment from 1 September 1979.

(LS 5/79 d) CHEMISTRY TECHNICIAN (Hydrology/Primary Production Team)

A chemistry technician is required to assist with hydrological and primary production studies The work mainly involves the automated photometric analysis of nutrient chemicals including trace elements, and measurements of primary productivity using radioisotope fixation techniques. The individual selected will be based at the British Antarctic Survey research laboratories in Cambridge and will spend several months each year at sea on RRS JOHN BISCOE.

Qualifications: Applicants must have at least an HNC in chemistry. Experience with chemical auto-analysers and atomic absorption spectrophotometers is desirable but not essential as training will be given.
Appointment from 1 September 1979.

TERRESTRIAL BIOLOGICAL PROJECTS

(LS 4/79) MAMMALOGIST to study the extent and nature of Antarctic fur seal, *Arctocephalus gazella*, pup mortality on land, to investigate any relationship between mortality and density of breeding fur seals and to evaluate the role of mother-pup behaviour in such circumstances. The successful applicant will work at Cambridge for 6 months before leaving to work at South Georgia for three full field seasons commencing November 1979 and he will overwinter during 1980. He will be supported by a field assistant. It is planned that he will return to Cambridge for the 1981 Antarctic winter, returning to South Georgia for the third summer field season Thereafter he will be employed for two years in Cambridge to analyse and write up the results of his field work.

Qualifications: At least an Upper Second Class Honours degree in zoology coupled with appropriate field work or postgraduate experience.

The post is available from 1st May, 1979 and must be taken up by early July.

(LS 6/79) Vacancy for a TERRESTRIAL BIOLOGICAL ASSISTANT/TECHNICIAN to work at South Georgia or Signy Island. He will assist with current terrestrial field programmes and will maintain routine environmental monitoring programmes, equipment and biological stores. The successful candidate will undertake a period of inital training in Cambridge and assist with the preparation and dispatch of equipment for the succeeding season's terrestrial research programme.

Qualifications: Applicants should hold appropriate technical or scientific qualifications and have established experience in relevant techniques. A suitable Honours, Pass Degree, HNC or appropriate Laboratory Technician qualifications are acceptable.

Appointment from 1 September 1979. At first the individual selected will be based in Cambridge. Approximately 2½ years will be spent in the field after sailing for the Antarctic in October 1979.

Salary: For posts ES 1/79, ES 2/79, ES 3/79, ES 4/79, ES 5/79, ES 6/79 and LS 1/79 from £3689 depending on qualifications and experience.

For posts AS 1/79, AS 2/79 and AS 3/79 from £2890 depending on qualifications and experience, plus a supplement of £444.60 for periods of service in Antarctica.

For posts LS 4/79, LS 5/79a and LS 5/79b from £3689 depending on qualifications and experience.

For posts LS 5/79c, LS 5/79d and LS 6/79 from £2890 depending on qualifications and experience, plus a supplement of £444 60 for periods of service in Antarctica.

Subject to satisfactory service, Officers are eligible for a terminal payment equal to 10% of selary for service in the Antarctic.

Tax for wintering personnel is low (British Antarctic Territory or Falkland Island Dependencies rates).

Quarters, clothing, messing and canteen stores are provided free of charge while Officers are serving in the Antarctic.

ELIGIBILITY· Applicants should be male, single and aged between 21 and 35
Applications will be considered from students who expect to graduate in 1979.

For further information and an application form, please write (quoting post reference number) giving full details of qualifications and experience to:

The Establishment Officer, British Antarctic Survey, Madingley Road, Cambridge CB3 0ET.
Closing Date: - 16th February 1979.

BIOLOGISTS

...to help develop natural history exhibitions

The British Museum (Natural History) is an institution for taxonomic research and has world wide collections of animals, plants and minerals. The Department of Public Services is responsible for the dissemination of information through educational conferences, written publications and exhibitions.

As members of a team within the Department, the successful candidates will work with designers, script-writers and educational technologists on the development of new natural history exhibitions The traditional display is being replaced by a completely new scheme designed to present an integrated view of modern biology. The biologists appointed will take responsibility for the organisation and presentation of subject matter and will maintain a close liaison with designers to specify the content and structure of exhibits.

Candidates, normally aged under 27, should have an honours degree or equivalent in biology, zoology, botany or other closely related discipline. The ability to work to strict deadlines is essential.

The appointments will be for 3 years, although subsequent permanent appointment is a possibility.

Salary in the range £3300—£4880 with starting salary according to qualifications and experience.

For further details and an application form (to be returned by 16 February 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours)

9368(A)

IMMUNOLOGIST/ VIROLOGIST

Two positions are available immediately at the Assistant Professor level for a Cellular Immunologist and a Virologist to work in the Bovine Leukemia Research Unit Applicants should have a Ph D or D.V M. degree with post-graduate training in the appropriate discipline.

Qualified applicants should send a résumé, copies of representative publications and the names of three people who may be contacted for references to: Dr Jorge F Ferrer, Chief, Section of Viral Oncology, University of Pennsylvania School of Veterinary Medicine, New Bolton Center, R.D 1, Kennett Square, Pa. 19348 9298(A)

INSTITUTE OF DERMATOLOGY

(University of London)

TECHNICIAN

required to join the research staff, currently investigating the role of pharmacological mediators of inflammation in human skin disease The successful candidate will undertake analysis of biological samples by radioimmunoassay techniques

Applications, giving full details of age, experience, qualifications and the names of two referees, should be sent to: Dr N A. Plummer, Institute of Dermatology, Homerton Grove, London E9 6BX. 9384(A)

ROYAL ALEXANDRA HOSPITAL FOR CHILDREN

Camperdown, N.S.W Australia

BIOCHEMIST

Applications are invited for the new position of Biochemist (Principal Scientific Officer) within the Department of Biochemistry in the Hospital's Institute of Pathology

The Hospital is a 400 bed Paediatric Teaching Hospital of the University of Sydney and offers a comprehensive range of clinical and laboratory services

The new appointee will assist the present Biochemist (Dr L Webster) in the routine work of the Department and will have special responsibilities in the development of new tests and techniques in the area of clinical paediatric chemistry. He/she will closely liaise with the Hospital's clinical staff and participate in the training programme of clinical and laboratory staff.

Applicants should hold a Ph D degree in Biochemistry or its equivalent, previous experience in clinical chemistry would be an advantage

Salary range $A21,049 to $A26,145 per annum.

Further information is available from Dr R K Oates, Director of Medical Services

Applications including the names of two referees should be addressed to the undersigned as soon as possible
J S Yu, General Superintendent

9283(A)

UNIVERSITY OF TORONTO

Physiology/Biochemistry

Applications are invited for two research appointments in the general area of gastrointestinal physiology, anaerobiasis and carbohydrate/protein intermediary metabolism

(a) Professional Associate Appropriate doctorate and postdoctoral experience required Initial appointment up to 5 years, renewable Salary scale floor $16,000

(b) Postdoctoral Fellow Two-year appointment Initial Salary in range $11,000 to $12,000

Applications and the names of two referees to

Professor D F Mettrick,
Chairman,
Department of Zoology,
University of Toronto,
Toronto, M5S 1A1, Canada

UNIVERSITY OF STRATHCLYDE
DEPARTMENT OF NATURAL PHILOSOPHY
PROFESSOR OF EXPERIMENTAL PHYSICS

Applications are invited from appropriately qualified and experienced candidates for appointment to the newly established Professorship in Experimental Physics which will involve a period of years as Chairman of the Department of Natural Philosophy Applicants should have experience in one or more areas of Experimental Physics and be capable of directing postgraduate teaching and research

The post will be remunerated within the Professorial range for universities with U S S benefits

Application forms and further particulars (quoting 5/79) may be obtained from the Registrar, University of Strathclyde, Royal College Building, 204 George Street, Glasgow G1 1XW, with whom applications must be lodged by February 28, 1979 9395(A)

UNIVERSITY OF ST ANDREWS
DEPARTMENT OF ANATOMY AND EXPERIMENTAL PATHOLOGY

Applications are invited for the post of Technician (Grade 4) in the above Department The successful applicant will take charge of the dissecting room and embalming suite, participate in the preparation of material for display in the departmental museum and assist with the preparation of teaching material

Salary at appropriate point on scale £2,955 to £3,402 per annum (under review) Applications, with the names of two referees, should be sent to The Establishments Officer, The University, College Gate, St Andrews, Fife by February 8, 1979 9427(A)

CSIRO AUSTRALIA
Research Scientist
Division of Animal Health
Glebe, NSW

CSIRO has a broad charter for research into primary and secondary industry areas The Organization has approximately 7,000 employees—2,300 of whom are research and professional scientists—located in Divisions and Sections throughout Australia

Field: Immunochemistry/Microbiological Chemistry

General: The Division has a major programme on infection and immunity with a substantial interest in immunity at mucosal surfaces in relation to helminth parasites and microbial agents An immuno-chemist/microbiological chemist is now sought to work at the McMaster Laboratory in the above programme

Duties: To carry out research into aspects of immunity to gastro-enteric infections, especially collibacillosis Attention could be directed initially to fractionation of *E coli* antigens and assaying for immunogenicity The appointee would be encouraged to collaborate with others in the programme

Qualifications: A Ph D degree in a relevant discipline, or equivalent qualifications, supported by satisfactory evidence of research ability and experience appropriate to the field of study

Salary: Research Scientist or Senior Research Scientist · $A15,422 to $A22,405 p a. An outstanding applicant may be considered for appointment at a higher level

Tenure. Indefinite with Superannuation

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 201/566, should reach —

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 28th FEBRUARY, 1979

Applications in U S A and Canada should be sent to.—

Tropical Products Institute
Culham, Oxon

Food Technologist

. . . to join the Non-Cereals Section of the Institute working on processing problems for a wide range of fruit and vegetables In addition the food technologist will take an active part in the current work of the Section, which includes various projects in sugar and starch processing and the maintenance of formal and ad hoc heat preservation training programmes. The Section has extensive facilities including a transportable cannery used for training, varietal research and local preparation of bottled and canned samples for marketing trials in producing areas. There are opportunities to undertake overseas project work.

Candidates, normally aged under 30, must have a degree or equivalent in an appropriate discipline. Practical experience of commercial food processing is highly desirable. *Final Year Students may apply.* Appointment as Higher Scientific Officer (£4100–£5450) or Scientific Officer (£2840–£4410) according to qualifications and experience. Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by 23 February 1979) write to Miss C A Hall, Tropical Products Institute, 127 Clerkenwell Road, London, EC1R 5DB. *Please quote ref SA/96/JD.*

THE BRITISH PETROLEUM COMPANY LIMITED
SENIOR RESEARCH FELLOWSHIP

Applications are invited by the Council of the Royal Society for The Royal Society — British Petroleum Company Limited Senior Research Fellowship, established by means of a five-year grant from the British Petroleum Company Limited for research in a subject field associated with the exploration, production and transport of fossil fuels and/or with the physical, chemical and mechanical properties of materials used in these operations The Fellow will be expected to have an interest in the application of his research to practical problems The appointment will be tenable in any appropriate university department or research Institution in the United Kingdom approved by the Council of the Royal Society Candidates, who must be citizens of the United Kingdom or the Commonwealth, must supply the usual personal details and give two referees Testimonials will not be considered The subject of the proposed research, and where it would be done, together with the name of the head of the department, whose consent should first be obtained, must be stated

The appointment, which will be subject to the Society's general regulations governing research appointments, will be tenable for five years from October 1, 1979 (or another date to be arranged) Applicants should preferably be under 45 on October 1, 1979 The stipend scale will be £8,031 by £252 to £8,787 by £249 to £9,036 per annum, and the point of entry will be determined by Council Superannuation benefits will be provided Some provision for research expenses will be available

Applications should be made on forms to be obtained from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG, and returned by March 31, 1979

9364(E)

POSTDOCTORAL FELLOWSHIP

Available from April 1, 1979 for a Ph D Graduate in biochemistry, virology, or related area interested in studying the structure and replication of mammalian and avian R N A viruses Applicants must have received the Ph D degree no earlier than April 1, 1978 Salary is $12,000 for the first year and $13,350 for the second.

Send curriculum vitae and references to Dr D G Scraba, Department of Biochemistry, University of Alberta, Edmonton, Alberta T6G 2H7, Canada

The University of Alberta is an equal opportunity employer 9378(E)

THE ROYAL SOCIETY
BRITISH GAS SENIOR RESEARCH FELLOWSHIP

Applications are invited by th Council of the Royal Society for Tl Royal Society—British Gas Senk Research Fellowship for origin scientific or technological research a field of mathematics, chemistr physics or engineering (includu metallurgy and materials science, flu mechanics, thermodynamics, combustion, heat transfer, biochemistry, at computer science) related to the pr duction, transmission and use natural gas and its substitutes.

Candidates, who must be citizens the United Kingdom or the Commo wealth, should supply the usual pe sonal details and two referee Testimonials will not be considere Candidates should state the subject the proposed research and where will be undertaken It is expected th the successful candidate will spend significant proportion of his or h time in direct collaboration with I dustry; evidence of existing contac would be helpful Applicants shou obtain and give evidence of conse from the head of department or oth authority in the university and/or i dustrial establishments in which th research will be done.

The appointment which will be su ject to the Society's general regulatio governing research appointments, w be tenable for five years from Octob 1, 1979 (or another date to b arranged), and may exceptionally b renewable for a further two year such renewal being considered at th end of the fourth year of tenur Applicants should preferably be und 45 on October 1, 1979 The prese stipend scale is £8,031 by £252 £8,787 by £249 to £9,036 per annur and the point of entry will be dete mined by Council Superannuatic benefits will be provided Some pr vision for research expenses will b available

Applications should be made forms to be obtained from the Exec tive Secretary, The Royal Society, Carlton House Terrace, London SW1 5AG, and should be received n later than March 31, 1979 9365(E)

THE ROYAL SOCIETY
SENIOR RESEARCH FELLOWSHIPS

Applications are invited by tl Council of the Royal Society for to three Royal Society Senior Resear Fellowships for research in any scie tific subject, established by funds fro the Parliamentary Grant-in-aid. Th appointments will be tenable in a appropriate university department research institution in the Unit Kingdom approved by the Council the Royal Society Candidates, wh must be citizens of the United Kin dom or the Commonwealth, mu supply the usual personal details a give two referees Testimonials w not be considered The subject of tl proposed research, and where it wou be done, together with the name the head of the department, who consent should first be obtained, mu be stated

The appointments, which will b subject to the Society's general reg lations governing research appoir ments, will be tenable for five yea from October 1, 1979 (or another da to be arranged) and may be renewat for a further two years Applicar should preferably be under 45 October 1, 1979 The present stipe scale is £8,031 by £252 to £8,787 £249 to £9,036 per annum, and t' point of entry will be determined l Council Superannuation benefits w be provided Some provision for r search expenses will be available

Applications should be made forms to be obtained from the Exec tive Secretary, The Royal Society, Carlton Terrace, London SW1Y 5A and returned by March 31, 1979

9363(E)

FELLOWSHIPS continued

RESEARCH FELLOWSHIPS

Two postdoctoral Fellowships available for three years in the I C.R.F. Medical Oncology Unit, St Bartholomew's Hospital Salary range £4,882 to £6,080 plus £450 L.W.

1) A cytogeneticist is required to identify chromosomal abnormalities in non-Hodgkin's lymphoma and leukaemia, and to relate these abnormalities to the class of tumour defined by pathological and immunological criteria. Experience of chromosome banding techniques is essential, and a background knowledge of immunology or cytochemistry desirable.

2) An immunologist is required to study the distribution of malignant lymphoma cells and their precursors in lymph node and bone marrow biopsies of patients with lymphoma. Experience in detection of surface antigens, preparation and purification of antisera, or surface phenotyping techniques is considered essential.

Applications with curriculum vitae and two referees to Staff Department, Imperial Cancer Research Fund, Lincoln's Inn Fields, WC2. Closing date March 19, 1979. 9394(E)

RESEARCH FELLOWSHIP

Imperial Cancer Research Fund Laboratories,
Mill Hill, NW7

A postdoctoral Fellow is required to join a group working on the genetic and biochemical analysis of certain heat activated loci in Drosophila melanogaster, using cloned DNA fragments to investigate their organisation and expression. Experience in molecular biology desirable.

Appointment will be for three years. Salary with entry according to qualifications and experience within range £5,332 to £6,530.

Further information from Dr Ish-Horowicz (01-959 3236). Applications with curriculum vitae and names of two referees should be sent to the Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields WC2A 3PX by February 24, 1979

9428(E)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF PHYSICS

ESEARCH FELLOWSHIP IA

Applications are invited for a post-ctoral Research Fellow to join the edical Applications group in the partment of Physics, to work on e measurement of fast-neutron ectra in tissue with a view to timising conditions for fast-neutron erapy Previous experience with clear instrumentation, neutron ectroscopy, and/or computing uld be advantageous This post is pported by the M R C

The post is tenable for three years om March 1, 1979 Starting salary ll be on the appropriate point of e Research Fellow Grade IA scale, ,883 to £6,555, plus superannuation arting salary will not exceed £4,882

Further particulars are available om the Assistant Registrar, Science d Engineering, University of Bir-gham, P O. Box 363, Birmingham 5 2TT, to whom applications (three ies) including curriculum vitae l naming three referees should be t by Monday, February 19, 1979 lease quote ref ND2. 9371(E)

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF PHYSICS

RESEARCH FELLOWSHIPS IN CRYOGENICS

Applications are invited for postdoctoral fellowships to work on the following projects

(1) Heat transfer in the reboiler/condensers of cryogenic plant, using model rigs and a full length test section
(2) Complex convective flow in stratified cryogenic vapours and liquids using Laser Doppler Anemometry
(3) Heat transfer and fluid behaviour of helium at 3,000 r p.m. for the development of large superconducting machines

Applications should have experience in mechanical/chemical engineering or low temperature physics

Salary in range up to £5.367 plus U S S benefits

Applications with names of two referees should be sent to Mrs E C P Sears, Staffing Section, The University, Highfield, Southampton SO9 5NH Please quote reference no 1607/R/Na. 9290(E)

LANCHESTER POLYTECHNIC

Coventry

Department of Biological Sciences

Postdoctoral Research Fellowship

(Tenable for up to 3 years from March 1, 1979)

£4,101 - £6,568

THE JOB The project is funded jointly by the SRC and ICI and involves the development of a method for the *in vitro* culture of perifused hepatocytes supported in a 3-dimensional matrix and its application to toxicological studies

REQUIRED Experience in animal cell culture and biochemistry Knowledge of cytological procedures would be an advantage

For further information applicants may contact Dr Sturdee or Dr Crisp by telephoning Coventry (0203) 24166

Faculty of Applied Science

Research Assistant in Cardiac Pacing

(Tenable for 1 year from March 1, 1979)

£3,192 - £3,330

THE JOB A statistical survey of patients with artificial cardiac pacemakers is required to attempt to identify those factors which cause a rise of stimulation threshold in certain patients The required collection of data will involve close collaboration with cardiac pacing centres in a number of hospitals

REQUIRED Applicants should have either an appropriate Honours Degree, or an appropriate HNC plus relevant experience

For further information applicants may contact Dr. Economides or Dr Duckers by telephoning Coventry (0203) 24166

For application forms and further particulars for the above posts please apply in writing enclosing a foolscap stamped and addressed envelope to the Personnel Officer, Lanchester Polytechnic, Priory Street, Coventry CV1 5FB, applications returnable by February 19, 1979 9404(E)

LINCOLN COLLEGE

(University College of Agriculture)
New Zealand

POSTDOCTORAL FELLOWSHIP

The Council of Lincoln College invites applications for a Post-Doctoral Fellowship tenable in the fields of Agricultural Microbiology (Ethanol Fermentation and/or Symbiotic Nitrogen Fixation), Entomology (Pest Management), or Environmental Sciences (Regional Development)

The object of the award is to contribute to the research programme at Lincoln College In addition to carrying out research, the successful applicant will be expected to participate in limited teaching activities without further emolument

The Fellowship will have a total value of NZ$10,000, part of which will be available for fares Tenure will be for one year in the first instance, but may be extended at the discretion of Council.

Conditions of appointment may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the College

Applications for this Fellowship close on April 30, 1979. 9421(E)

UNIVERSITY OF ABERDEEN

DEPARTMENT OF CHEMISTRY

POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited from graduates in Chemistry or Physics to work with Dr J. L Duncan and Dr D C McKean on Infra-red Spectroscopy The successful applicant will undertake research on a variety of topics using a computer controlled, high resolution Fourier transform spectrometer Previous interactive experience, and an ability to develop software and undertake electronic maintenance is desirable

The post is funded by the Science Research Council and is available from April 1979 Appointment will be for one year in the first instance, with possible extension up to a maximum of three years

Commencing salary within Range 1A, £3,883 to £4,382 per annum, with appropriate placing

Further particulars from The Secretary, The University, Aberdeen, with whom applications (two copies) should be lodged by February 23, 1979

9375(E)

POSTDOCTORAL FELLOWSHIP

National Institutes of Health, U S A

To start any time between August and November 1979 Individual trained in cell biology, genetics, and/or biochemistry, to work in laboratory of L Leive on eukaryote membranes Fellowship for non-U S citizen, newly or up to four years postdoctoral Contact Dr Leive at NIH, 4/116, Bethesda, Md 20014, USA 9457(E)

FELLOWSHIPS—continued

EMBO

European Molecular Biology Organization

LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY

SPRING 1979 AWARDS

Next deadline: February 20, 1979

The long term fellowships will usually be for a period of up to one year but applications for a renewal for a second year are considered. To be eligible a candidate must hold a doctor's degree. Preference will be given to European and Israeli applicants wishing to work within Europe or Israel EMBO long term fellowships are not, however, awarded for exchanges between laboratories within any one country. Applications for fellowships to be held outside Europe and Israel are considered but they have a lower priority, as do applications from non-European scientists wishing to work in Europe or Israel.

The deadline for applications for the 60 fellowships to be awarded in April 1979 is February 20, 1979. Because the selection procedure involves an interview this deadline should be respected.

Application forms and further details may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 1022.40, F.R. Germany.

9278(E)

STUDENTSHIPS

AGRICULTURAL RESEARCH COUNCIL STUDENTSHIP

Applications are invited for a Studentship to work in the Protein Section of the Meat Research Institute.

The project is to investigate the turnover and remodelling of the connective tissues in relation to growth and development.

This will consist of radioactive incorporation studies together with autoradiography, the chemical analysis of connective tissue components and an examination of the cellular mechanisms for resorption of tissue.

The project is expected to form the basis for a Ph.D thesis in the University of Bristol and the appointment will commence in October, 1979.

Candidates should possess a First or Upper Second Class degree in Biochemistry

Further particulars of the award and allowances together with Application Forms may be obtained from the Personnel Officer, Agricultural Research Council, Meat Research Institute, Langford, Bristol BS18 7DY

9431(F)

NATIONAL VEGETABLE RESEARCH STATION A R C RESEARCH STUDENTSHIP Applications are invited for an Agricultural Research Council postgraduate Studentship for research on the mode of action of systemic fungicides active against *Bremia lactucae* (lettuce downy mildew) and variation for sensitivity in the fungus to these chemicals The work will involve laboratory, glasshouse and field studies The studentship will be tenable from October 1, 1979, for up to three years at the NVRS with a view to reading for the degree of Ph D at Birmingham University Candidates should hold or expect to obtain in 1979 a first or upper second class Honours degree in Plant Science with particular emphasis on at least one of the following disciplines. plant pathology, plant biochemistry, plant protection and genetics Further particulars and an application form (to be returned by February 20, 1979) from the Secretary, National Vegetable Research Station, Wellesbourne, Warwick CV35 9EF 9450(F)

Strathclyde Regional Council—Department of Education

GLASGOW COLLEGE OF TECHNOLOGY

DEPARTMENT OF BIOLOGICAL SCIENCES

S.R.C. Studentship in Biochemistry or related subject areas to work on the "sodium pump" in essential hypertension A first or upper second class honours degree is a prerequisite for the award. The post has to be filled by April 30, 1979. Write or phone for further particulars to Dr T. Duffy, Department of Biological Sciences, Glasgow College of Technology, Cowcaddens Road, Glasgow G4 0BA. Telephone 041-332 7090, Ext. 283 or 340 not later than February 12, 1979.

E. MILLER Director of Education

9425(F)

GRASSLAND RESEARCH INSTITUTE

Hurley, Maidenhead, Berkshire

POSTGRADUATE STUDENTSHIP

Applications are invited for the award of a postgraduate studentship funded by the Agricultural Research Council and tenable at the Grassland Research Institute for a period of three years commencing on October 1, 1979.

The Grassland Research Institute is an Associated Institutio of the University of Reading, where the successful applican will be registered for a higher degree.

There is a choice of projects and candidates should indicate clearly for which project they are applying.

Project 1 To identify the important factors influencing the economic assessment of dairy systems, including the effects of climate, soil and management. The study will involve the construction of a model to determine the response of the system to these factors with a view to improving output Candidates should have or expect to obtain a first or upper second class honours degree in a quantitative subject and have an interest in agriculture.

Project 2 To investigate the effects of early season management and water availability on the nitrogen uptake an seasonal pattern of grass growth The investigation will b field based and will include studies of tillering, herbage growth, nitrogen uptake and soil water.

Candidates should have or expect to obtain a first or uppe second class honours degree in Agricultural Botany or Plan Science.

The studentship comprises a tax-free maintenance allowanc of £1,610 per annum plus compulsory fees and travellin expenses.

Applications by February 28, 1979, to the Secretary, fro whom further details may be obtained.

9444(F)

A.R.C. ANIMAL BREEDING RESEARCH ORGANISATION

DEPARTMENT OF APPLIED GENETICS

POSTGRADUATE RESEARCH STUDENTSHIP

Applications are invited for an A R C Research Studentship tenable i Edinburgh for three years from October 1979

The project deals with the evaluation of foreign pig breeds, involvin statistical analysis of experimental data and theoretical study of methods The successful applicant will be expected to register for a higher degree and there may be an opportunity for additional coursework in Anima Breeding.

Candidates should possess, or expect to obtain, a good honours degre in agricultural science, biology or statistics, and have an interest i biometrical work

Awards include a tax-free allowance, payment of fees and other ex penses Full details and application forms are available from the Secre tary, A R C Animal Breeding Research Organisation, West Mai Road, Edinburgh EH9 3JQ, Scotland Applications should be made b March 3, 1979

9439(F)

AGRICULTURAL RESEARCH COUNCIL

INSTITUTE FOR RESEARCH ON ANIMAL DISEASES

POSTGRADUATE STUDENTSHIP

Applications are invited from suitably qualified candidates for a Studentship, funded by Standard Telecommunications Laboratories in conjunction with Hoechst Ltd., for work leading to a higher degree

The objective of the research will be to develop new methods for prevention of diseases due to trace element deficiencies in cattle and sheep and this will involve measuring the absorption, retention and excretion of the copper and selenium in a number of compounds currently used for the control of deficiency states and investigating the advantages and limitations of using the newly-developed controlled-release glasses

Candidates should possess a First or Upper Second Class degree in a biological science or expect to obtain this qualification at the end of the academic year.

Application forms from Secretary, Agricultural Research Council, Institute for Research on Animal Diseases, Compton, Newbury, Berks., quoting reference 304

SYMPOSIA

THIS TENTH ANNUAL INTERNATIONAL SYMPOSIUM

will deal with the control of national food quality, chemical, metabolic and microbiological aspects, health foods, additives and contaminants, healthy eating, special processing and packaging aspects, food and the brain and infant nutrition. Speakers will include experts from the U.K., U.S.A., Holland, Germany, Italy, Switzerland and Poland. The keynote lecture, "Food and Health from Conception to Extreme Old Age", will be given by Dr Elsie M. Widdowson.

Programmes containing application forms are available from:

National College of Food Technology
(University of Reading)
St. George's Avenue
Weybridge, Surrey 9453(M)

COURSES

INSTITUTES OF PSYCHIATRY, NEUROLOGY AND OPHTHALMOLOGY

(British Postgraduate Medical Federation,
University of London)

POSTGRADUATE COURSE IN NEUROCHEMISTRY

This is a ONE-YEAR Course leading to the degree of M.Sc. in Neurochemistry. It offers graduates in science and medicine training in basic and applied neurochemistry. The Course consists of lectures, seminars and laboratory work and, in the second and third terms, research on a neurochemical topic.

Applicants should have an honours degree in Biochemistry or a Biological subject with some Biochemical component, or be Medically qualified. The Course is recognised by the Medical Research Council as an Advanced Course for the award of Training Scholarships to suitably qualified applicants.

Application for the Academic year October 1979 to July 1980 should be addressed to the Secretary, Course in Neurochemistry, Department of Biochemistry, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF, England. 9443(D)

BRITISH COUNCIL COURSE

THE LYMPHOCYTE

2–14 December 1979

The aim of this course is to familiarise participants with the latest advances in Britain in the immunology of the lymphocyte and to update their knowledge of current concepts of the role of the lymphocyte in adaptive immunological processes. Lectures, discussion periods, demonstrations and some practical work will highlight central developments such as the role of the major histocompatibility complex and recent technological advances.

The Directors of Studies will be Professor I. M. Roitt and Dr P. M. Lydyard of the Middlesex Hospital Medical School, London, where the course will be based.

Members of this course will be postgraduates, mainly working outside Britain, who are laboratory investigators or clinicians with 2–3 years experience in immunology or allied fields.

Fee: including demi pension, £475.

Application forms, which should be in London by July 1, 1979, are available from your local British Council Representative or from The Director, Courses Department, The British Council, 65 Davies Street, London W1Y 2AA, Great Britain. 9458(D)

EMBO COURSE ULTRACRYOMICROTOMY

An advanced practical course on ultracryomicrotomy will be held at EMBL Heidelberg from May 2-4, 1979. Instructors will include Dr K. Tokuyasu, UCLA San Diego. Participants will be limited to a maximum of 10 and preference will be given to those having some experience with the technique. Limited funds will be available to cover travel expenses in some cases. Applicants should write before March 1, giving details of relevant interests to Dr G. Griffiths, EMBL, Postfach 10.2209, 69 Heidelberg, Fed. Rep. Germany.

9430(D)

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF METALLURGY AND MATERIALS SCIENCE

ONE YEAR M.PHIL. COURSE IN MATERIALS TECHNOLOGY

The University has introduced a new degree, the Master of Philosophy in Materials Technology. The course aims to give training in the Materials research techniques and technology most relevant to the needs of development laboratories and industrial concerns.

Each student will undergo training in collaboration with a particular industrial firm. The lecture programme will be tailored to individual needs and the student will undertake a research project chosen for its direct relevance to the collaborating concern. Applications are invited from persons who possess or expect to get a good honours degree in subjects such as Metallurgy, Materials Science, Engineering Physics and Chemistry.

The course has been accepted as qualifying for the award of S.R.C. Advanced course Studentship. Applications and enquiries should be sent to the Course Convenor, Dr B. Ralph, Department of Metallurgy and Materials Science, University of Cambridge, Pembroke Street, Cambridge. 9380(D)

ELECTRICAL DISCHARGES IN IGNITION AND COMBUSTION

A Post Experience Course will be held at Imperial College from May 1 to 3, 1979. Details from Dr M. D. Carabine, Chem. Eng. and Chem. Tech., Imperial College, London SW7 2BY. Tel: 01-589 5111, Ext. 1906.

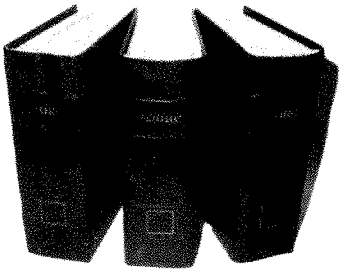
Nature Binders



Keep your copies of Nature protected in durable black PVC binders:

*** 20 plastic retention strips mean no loose parts, wire, or complex loading systems**

*** title blocked in gold on spine**

*** panel on spine for your own references**

Each binder is designed to take two volumes of Nature; three binders will serve for a year.

Prices (including postage):
UK £3.00 each, three for £8.00
Rest of World US $6.00, three for US $16.00
Orders with correct remittance should be sent to:
Nature, Circulation Department,
Macmillan Journals Ltd,
Brunel Road, Basingstoke,
Hampshire RG21 2XS, England.

W 'v made lif easier for the busy biochemist.

"For swift and accurate quantitative cell information, the GN5 Integrating Microdensitometer is a real discovery," she declared. "It makes cell study much easier and far outstrips manual methods."

Start to reduce your work load by asking for technical literature on the GN5. Use the journal reply system or call us, Barr & Stroud Limited, (Dept. N3),
Melrose House, 4-6 Savile Row, London W1X 1AF.
Telephone: 01-437 9652. Telex: 261877.

The GN5 Integrating Microdensitometer.

Accuracy and speed are perhaps the greatest benefits the compact and reliable GN5 brings to the analysis of your cell preparations. Scans are of only 4 second duration yet give 0.25 micron resolution. For histochemical and cytochemical studies, accuracy is better than ± 1% over an optical density range of from less than 0.1 to greater than 2.5. And there are other important features, including area measurement, electronic masking and narrowband illumination. A remarkably fine addition to your laboratory, and ergonomically designed to ensure that it is a comfortable one too.

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**, 1 (1975) and **264**, v, 11 Nov. (1976).

Substance P causes direct depolarisation of neurones of guinea pig interpeduncular nucleus *in vitro* — *N. Ogata* 480

Populism . . . elitism . . . or a middle way?

THE newly formed Science, Technology and Society Association started life with a suitably large splash last week in London by having Mr Tony Benn, UK Secretary of State for Energy and the association's president, talk on the democratic control of science and technology. The association has emerged from the SISCON (Science in a Social Context) project which, over the past few years, has brought together various groups in higher education in Britain interested in the broader issues of science. The plan now is to reach beyond the academic world and not just into other areas of education. Its first newsletter speaks of hoping to draw members from industrial managers, trade unionists, politicians, members of the public "to confront scientists with the implications of their researches", teachers and journalists. An unfortunate omission is mention of those very scientists and technologists whose work raises so many issues. And at the first meeting there was also a sad lack of those same scientists and technologists.

Mr Benn's not entirely unpredictable line was that the questions raised by developments in science and technology were too important to be the subject of closed discussion amongst an elite. He drew two examples, from the military world and the field of nuclear power. The disciplined hierarchy of the military, comparable with monastic orders, could have all sorts of influences of which the public were totally unaware; enormous expenditures in what was now a highly technological defence force were essentially secret. Again, nuclear power, regardless of the merits of those who have devoted their careers to it, raises the some problems of democratic control and tightfistedness over the flow of information. Mr Benn plans to postpone a decision on the commercial fast-breeder reactor for as long as possible, not because of doubts on the technological side but because, he claims, he is as yet not satisfied that the democratic machinery exists to bring out all relevant information.

One of the prices of high technology and high living standards, he pointed out, is a greater vulnerability of society to industrial disputes, technological and natural disasters and war. And as a consequence civil liberties can be eroded—we might find ourselves backing into a police state by means of high technology, and abandoning our values. We cannot, declared Mr Benn, discuss technology in isolation from the much neglected subject of societal values. And if we do not safeguard these values with democratic institutions we are in danger of trading liberties for colour television sets.

Mr Benn, of course, has great faith in the ballot box, in parliament and in fully informed ministers (not as managers so much as members of the public elected as it were to the board of directors) If the public, through elections, can have a voice in the country's social and economic policy, why not also in policy for science and technology?

It is possible to go a long way with Mr Benn's thinking on accountability, and yet to find the ballot box too facile a symbol of that accountability. As he himself admits, some do not vote for the government they believe to be most suitable but (for example) for the candidate who is for or against fluoridation. In all the complexity of motives for voting, and in all the manoeuvring a government does to try and ensure that it is re-elected, what hope that a stable policy for science and technology be central to anyone's thoughts? Yet without stability and rational policies, scientists and technologists who, more than almost any other sector of the community, can move in international circles will simply get up and go where the climate is more settled. And the idea of complex developments with necessarily vast ranges of uncertainty becoming an area of populist concern is bound to strike terror in the hearts of those patiently and quietly trying to accumulate the relevant knowledge

But whilst we ought to be wary of a sort of free-ranging democracy which is alien to science itself, if the obverse is a return to monastic secrecy, that too must be resisted. Certainly scientists and technologists are a very different breed from politicians, and distrust is to be found on both sides of the fence. But somehow we as scientists have to raise our deplorably low political awareness just as we have to hope that more than a handful of politicians like Mr Benn will find they can move freely and happily within the world of science and technology. Here the Science, Technology and Society Association should have a major role to play. One of its objectives should be to incorporate into the educational system more courses which will make potential scientists and technologists think about public issues. At present it is too easy to become fully qualified without such a training If this were to make for wiser, more mature judgement by us, the practitioners, and if at the same time an increased number of politicians were able to appreciate the issues in more than terms of short term gain, then science and technology policy, founded on rational dialogue, would benefit immeasurably. And that, presumably, is what Mr Benn would wish ☐

Doctors claim A-bomb tests linked to rise in child leukaemia deaths

David Dickson reports on a statistical survey in Southern Utah

RESEARCH workers at the University of Utah claim to have discovered a two-and-a-half fold increase in the leukaemia death rate among children exposed to fall-out from atomic bomb tests carried out in the Nevada desert in the 1950s.

In one of the first systematic studies of civilians exposed to fall-out from the tests, the research workers have found a particularly large increase in the number of leukaemia deaths in children born around 1951—the beginning of the testing period—and that leukaemia death rates returned to their previous levels after the testing was stopped in the early 1960s.

The results of the study have already been passed to federal officials in Washington in a series of meetings last month, but have not yet been published. And although the research workers are cautious about interpreting a correlation as indicating a causal relationship the results of the study will provide a major boost to over 100 cancer patients and relatives of those who have died from cancer in areas surrounding the test site, who are currently suing the US government for a total of $232 million in damages.

" This is the bombshell that is going to establish beyond doubt that these claims are on solid ground," Mr Stewart Udalla, a former Secretary of the Interior, who is now in private law practice and is pressing the case against the government, said last week.

Residents of Southern Utah have for years suspected that an apparently abnormal level in the number of cancers in the area was linked to fall-out from the A-bomb tests. The two towns of Parowan and Paragonah, for example, with a combined population of 1,800, experienced four cases of leukaemia from 1956 to 1967, two to three times the expected rate.

So far, however, evidence has remained sketchy and largely anecdotal, with insufficient data to establish any significant correlation. Two weeks ago, for example, it was learned that a study carried out in 1965 by a scientist with the US Public Health Service's Division of Radiological Health, who claimed to have shown an excessive level of leukaemia among residents of two Utah counties exposed to fall-out, was ignored and subsequently forgotten.

Interest in a possible correlation between the tests and civilian deaths was revived last year, when evidence was presented to a congressional subcommittee that an excessive incidence of leukaemia had occurred among soldiers who took part in exercises while the tests were underway (a claim which has recently been substantiated by the Center for Disease Control).

Such evidence prompted the University of Utah's research team, headed by Dr Joseph L. Lyon, of the Department of Family and Community Medicine in the College of Medicine, to carry out a detailed study of child deaths in the state between 1944 and 1975. The results of their study are about to be published in *The New England Journal of Medicine.*

Dr Lyon and his colleagues focused their attention on children under 15 who died in 17 counties in the south of the state, which experienced relatively high fall-out from 26 tests between 1951 and 1958. Radioactive debris from the tests was carried eastwards by the wind from the Nevada test site into Utah.

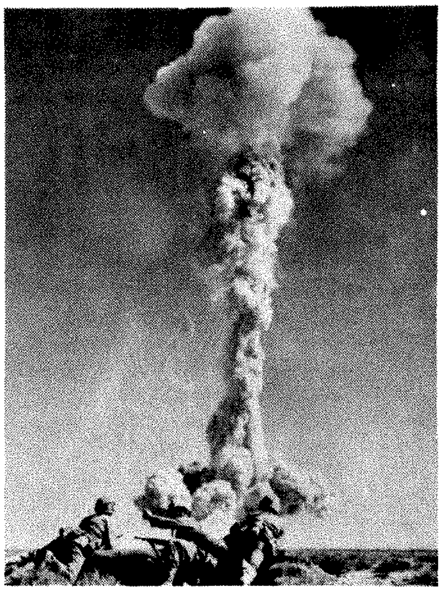
The children were divided into two groups for comparison: a "high exposure" group, who died 1951–58; and a "low exposure" group who died before 1951 or were born after 1958.

Analysis of the death certificates showed the leukaemia mortality rate among children in the low exposure group in these counties to be about half that in the remainder of the state, and indeed the rest of the US—a fact which is unexplained, but may be related to the ascetic life-style of the Mormon communities which predominate in the area.

In the high exposure group, however, although leukaemia mortality started off equally low, it climbed through the 1950s to reach a peak slightly higher than the US average in the early 1960s, subsequently falling back towards its previous level. This group did not reveal any excess for other childhood cancers.

The greatest excess in leukaemia deaths occurred in the 10–14 age group, where the number of deaths rose from between one and two per 100,000 to almost 10 per 100,000 around 1961—implying a particularly high incidence of leukaemia among those born towards the beginning of the testing period, with the disease causing death 10 to 14 years later.

The research workers found that there was a slightly lesser elevation in the 5–9 age group—those who were born around 1956—and little excess among the 0–4 age group. Furthermore the standard mortality ratio for the two groups for the whole age range was slightly higher for boys than for girls.



Nevada bomb test, 1952, watched by US marines

Even the children who lived in counties which had not experienced the high fall-out rates showed a slight increase in leukaemia mortality. But over half the excess deaths (16 out of 30) occurred in those counties which had been subject to the heaviest fall-out, even though these containd only 10% of the population.

Dr Lyon and his colleagues are being cautious about their results. They do not claim to have demonstrated that the excess leukaemia deaths were in fact due to the bomb tests, merely that there is a statistical correlation between the two. Their evidence is already being studied by other statisticians.

However, enough data has been produced by the study to convince others that when the Atomic Energy Commission told Utah residents in the early 1950s that the fall-out they were receiving was, to quote public statements, "far from hazardous" and presented "no danger" it was being grossly misleading—even admitting that the statements may have reflected the state of knowledge at the time.

Prompted by results such as those contained in the new study, President Carter has directed Mr Joseph Califano, Secretary of the Department of Health, Education and Welfare, to re-evaluate the findings of all earlier studies of the incidence of leukaemia in Utah, particularly in the south-west.

DHEW is expected to name the University of Utah researchers as the principal investigator in a major follow-up study. But whatever emerges, it may be too late to prevent what Mr Udall has called the "terrible tragedy" that took place 20 years ago. □

Budget cuts cause upheavals in earthquake research

David Dickson describes how a sociologist's misbehaviour has led to a major gap in efforts to restrict the damage caused by earthquakes

TWO YEARS ago, Los Angeles City Council member Howard Jarvis—later to achieve fame as author of California's tax-cutting Proposition 13—led a successful campaign on behalf of the city's apartment owners to prevent signs being posted on private buildings liable to collapse during an earthquake. Some months later, sociologists found in a survey that over 90% of the inhabitants of the city, where more than 20,000 buildings are considered to be inadequately protected against earthquakes, thought that the posting of such signs would be a good idea.

Professor Ralph Turner of the University of California in Los Angeles, who heads the research team which conducted the survey as part of a wider project, claims that if the results had been known previously, the city council might have acted differently, and that they illustrate the type of role that the social sciences could play in mitigating the damage caused by earthquakes.

Yet, as the result of congressional actions last summer, National Science Foundation funds for social science research in this area have been savagely cut back. The foundation has been forced to reject all proposals for new projects so that existing ones can be completed. And even in the next fiscal year, funds for such policy research, according to the budget request now being submitted to Congress, will only be one-fifth of the amount originally requested for 1979.

Two years ago, the picture looked very different. With growing concern about a (supposedly) imminent earthquake in California, President Ford requested in his last budget proposal that spending on earthquake hazard reduction programmes at the NSF be increased from $12 million in 1977 to $32 million in 1979 (with an even larger increase at the US geological survey). Last year President Carter responded to legislation passed by Congress by setting out a national earthquakes hazards reduction programme. This stated that earthquakes posed "perhaps the greatest single-event natural hazards faced by the nation" (estimates put the property at risk at $2,300,000 million), and assigned the NSF to carry out basic and applied research on earthquake engineering and policy.

Then along came Senator William Proxmire. During hearings on the NSF budget, it emerged that a professor of sociology at the university of Colorado, Dr J. Eugene Haas, who had received NSF contracts for more than $500,000 to carry out research into the socioeconomic and political consequences of earthquake prediction, had used the money for, among other things, taking his girl friend on a trip to Honolulu, Tokyo and Hong Kong.

Congress is seldom kind to social scientists, and this misbehaviour, for which Professor Haas was subsequently dismissed from the university, was sufficient for the House Appropriations Committee to reduce the NSF's request for earthquake hazard research from $26.4 million to $17.4 million. Within this total, the amount to be allocated to social science policy research was reduced from $4.8 million to $800,000, the remainder being divided between siting and engineering design studies.

NSF officials were accused by the appropriations committee of mismanaging the funds awarded to Professor Haas. They were also stung by the claim that similar work was being carried out in other agencies, since they say these agencies turn to the foundation for their research support. Nevertheless the result has been that the NSF has had to reject all new proposals for research on the policy aspects of earthquake mitigation.

After an earthquake: devastation on the sidewalk of a southern California town.

These projects involved assessing the reaction on social and political institutions of information about earthquakes, as well as of the earthquakes themselves. "It is not just a question of needing more research. This is a subject that has never been adequately developed because there has never been a long-term commitment to provide support", Dr Robert Olsen, a social scientist of the Seismic Safety Commission in Sacramento, California, who has chaired a panel on the potential contribution of the social sciences, said last week.

"Many of our problems in reducing earthquake damage relate to legal and institutional considerations that affect the use of technical knowledge and its translation into public policy. The budget reductions mean that the lack of sufficient high quality people willing to undertake such projects is likely to remain."

Dr Olsen's brother, and associate professor in political science at the University of Redlands outside Los Angeles, is one of those who have proposed a major study to the NSF for which he has been told there is no money. The project would involve a two-year investigation in the San Bernardino area of how seismic safety issues are perceived by decision makers. "We shall be putting the proposal in again, and if it flies, it flies. Otherwise this is the last shot. Personally, the lack of money is driving me back into more traditional areas of social science."

Some feel that, despite the tough budget year, the NSF could be more aggressive in its approach to Congress. At present the foundation is requesting a level of funding for 1980 little higher than that to which it was reduced in the current year. "We will do what we can to get this raised, but it would have been easier if they had asked for a little more", the aide to one Californian congressman said last week.

Others feel it may take a major earthquake before research money starts flowing in. According to Dr Carl Kisslinger, president of the American Geophysical Union, the mayor of Pinotep Nacional in Mexico has claimed that public reaction to an earthquake forecast by US scientists did more damage to the economy of his town than the 7.5 magnitude shock that hit the area last August. ☐

US scientists want 40% cut in defence spending

A GROUP of six scientists and military analysts has produced an "alternative military policy" for the United States which, it says, would buy a "better and safer defence" at only 60% of the cost of the present policy.

The Boston study group outlines its new strategy to reduce military spending in a 350-page book. *The Price of Defense,* which is being published shortly after President Carter has sent Congress a budget request for 1980 for a 3% real increase in defence spending.

The group says that the study is meant to "stimulate broad and serious debate of overall American military needs and foreign policy"—a debate which it claims has not taken place in the United States for many years.

Speaking at a press conference last week, Dr Martin Moore-Ede, professor of physiology at Harvard University, explained that the Boston group's proposed reduction of 40%—or $50 billion a year—in American defence expenditure would cut out "inertia, obsolescence and temptation: the inertia accounts for the entrenchment of high military budgets during peacetime, the obsolescence we cut are the easily-targeted, expensive and vulnerable remnants of the technological past, and the temptation we remove is the excess weaponry and forces that this nation possesses."

More specifically, the study recommends eliminating all of the United States' one thousand land-based intercontinental ballistic missiles over five years, although it concedes that a hundred of the latest Minuteman III ICBMs might be retained longer "as a hedge." All strategic nuclear bombers would also be retired, perhaps over eight years, on the grounds that they are "vulnerable, expensive and obsolete."

The Boston group argues that the retention of 31 Poseidon submarines, each carrying a maximum of 16 missiles, would leave the US with a virtually invulnerable nuclear deterrent sufficient to "wreck every Soviet and allied city and industrial district, plus many extra military targets". It sees no need for the new series of Trident submarines, the first two of which are under construction, and proposes cancelling them.

The Department of Defense's research and development activities would be severely pruned. The Pentagon would be left with only $100 million a year to spend on basic research: the group proposes to transfer the remaining $300 million to a new national technology foundation to "stimulate R & D in areas of expensive high technology where private industry is not yet willing to undertake the work". Applied research and development would be cut by two thirds.

The Boston group analysed the social effects of transferring $50 billion from the military to the civilian sector of the economy, and estimates that the net effect would be a gain of two million jobs "because defense dollars create far fewer jobs than monies spent in other sectors of the economy."

UNCSTD meeting split on transfer of technology

DESPITE considerable opposition, the transfer of technology to developing countries will occupy a prominent, if controversial, position on the agenda of the United Nations Conference on Science and Technology for Development, in Vienna next August.

This emerged from the third meeting of UNCSTD's preparatory committee, which ended in New York on Monday, and at which delegates from a number of developed countries—in particular the United Kingdom, the US and West Germany—had argued that the issues involved were already being adequately debated in other forums.

In an address to the meeting, for example the British delegate, Dr Dennis Osborne said that attempts to duplicate negotiations on a code of conduct for the transfer of technology already underway elsewhere in the UN system "would lead to confusion and delay in reaching agreement".

Many of the recommendations in the UNCSTD secretariat's preliminary draft programme of action on this topic were "unacceptable to my government in their present form," Dr Osborne said. However Mr Frank Joao da Costa, Secretary General of the conference, told the preparatory committee that the proposed agenda for Vienna and the draft programme merely reflected the wishes expressed by member countries—and that since the transfer of technology was high among the concerns of many developing countries in their national and regional papers, it would have to be addressed by the conference.

In its closing plenary session on Monday morning, postponed from last Friday to allow additional time for discussion, the committee accepted a resolution submitted by the Tunisian delegate on behalf of the Group of 77 to restructure the draft programmes of action under three 'target areas': reinforcement of the scientific and technological capacities of developing countries; restructuring the conditions of access to scientific and technological knowledge as an integral part of the new international economic order; and better coordination of the scientific and technological activities undertaken within the UN system.

THIRD WORLD TECHNOLOGICAL DEVELOPMENT
UNCSTD COMMITTEE STILL UNDECIDED

"If they delay long enough, the technology they give us will be out of date"

Despite agreement on the formal changes which they wish to see in the programmes of action, however, the Group of 77, which had established a working party during the committee meeting, were unable to come to any agreement on the substantive issues which the preliminary draft of the programme has raised.

Members of the group, to which over 120 developing countries now belong, have therefore agreed to hold a further meeting before the next preparatory committee meeting, which takes place in May, and to create a mechanism for continuing discussion of the issues up to UNCSTD itself.

According to some observers, it was this strategy on the part of the developing countries which led to the relative success of last year's UN conference on technological cooperation between developing countries. "If this is the case, then the game will have been worth a candle" one of them said.

Delegates at the meeting were unable to agree on whether there should be a fifth meeting of the preparatory committee before UNCSTD, although if such a meeting is called 26 June–6 July has been put aside for it in New York.

West Germany boosts research by one fifth

Germany is playing for a big lead in innovation, writes **Robert Walgate** from Bonn

ALMOST without debate, the *Bundestag* last month increased the budget of the West German Ministry for Research and Technology (BMFT) by 19.8% to DM5.5 billion. The emphasis is on stimulating innovation, not basic science. For example, the Deutsche Forschungsgemeinschaft (DFG), responsible for basic research in the universities, received only a 4% increase. But the ministry's programme for stimulating innovation jumped 129%.

There were also big increases in many of the directed programmes of the BMFT, particularly in electronics (32%), transport (58%), and energy, which rises 21% from DM1,720 million in 1978 to DM2,080 million in 1979. The non-nuclear research programme is growing particularly fast. It will reach DM533 million in 1979, 52% above its cost in 1978.

The increase in the transport budget represents confidence in the Erlangen Research Centre in Bavaria, where the government has already invested DM250 million in the Siemens, AEG, and Brown Boveri 450 km/h hovertrain. The investment in electronics will stimulate research in microprocessor technology.

The BMFT was not the only ministry to increase its research budget: the Ministry for Industry also announced a DM300 million boost for research in small and medium sized firms, to cover up to 30% of the cost of employing new research staff. It is hoped that this will not only correct the imbalance whereby some 90% of government-supported industrial research has been allocated to only 40 firms, but might also provide employment for the 50,000 or so un- or underemployed scientists in Germany.

Germany may be in a position of great economic strength at present, but it is certainly taking very seriously the challenges provided by its lack of natural resources, and the increasing industrial competition from Third World countries with their low labour costs. Germany seems determined to invest effectively in its brains. However there may be a more immediate reason for the success of the BMFT in this budget. The previous minister, Hans Matthoefer, is now Finance Minister in overall control of the budget, so Volker Hauff, the 38-year-old economist who now runs BMFT, has had a sympathetic ear.

However, the *Bundestag* itself showed little interest in the developments. Despite a two-day debate (23–24 January) on the whole German Budget, only the last 90 minutes (from 10.30 pm to midnight) were devoted to the affairs of the BMFT. A leading commentator on science politics in West Germany, Hartmut Altenmueller, wrote: "The interest that politicians and the public take in science was shown by the debate in the *Bundestag* last week. Zero." Only one parliamentarian, says Altenmueller, criticised the situation. This was Herr Laermann of the Centre Party, FDP (which has been taking an interest in ecology and the Kalkar fast breeder reactor lately). Laermann argued that it was time the *Bundestag* took an interest in the politics of science and technology before the government had formed its policy, made its mistakes, and presented the *Bundestag* with a *fait accompli*. But little attention was paid to his speech.

Technology minister Volker Hauff

On a longer perspective, however, German science politics is becoming increasingly interesting, and it would seem impossible that the *Bundestag* could ignore the issues. For example, Professor Helmar Krupp, Director of the Institut für Systemtechnik und Innovationsforschung (ISI), believes that there is a growing awareness in Germany that technology must be looked at through the eyes of labour: what is it like to work with technology, what influence does it have on life? Moreover, this concern, he feels, is not the exclusive property of the ruling SPD coalition. "The awareness is greater here in Germany that we must rely on high technology, that intensive work with raw materials will go out".

The government is increasingly turning to institutes like his own (it is similar to the Science Policy Research Unit at the University of Sussex in the UK) to ask for expert advice in matters of science and technology policy. For example, the DM300 million programme for stimulation of research in small and medium sized industry was designed within ISI in close cooperation with the ministry.

The energy issues, says Krupp, are much the same in Germany as elsewhere. But in basic science, Germany is facing some interesting questions. The Max Planck Institute for Plasma Physics in Garching, near Munich, is recovering rapidly from the blow of losing the joint European Tokamak (JET) project to Culham in the UK. It is now forming a proposal for a device not dissimilar in price to JET itself.

JET was delayed for some years by Brussels politics, and in some respects its design is dated. The Garching project, costing DM280 million, would be designed specifically to achieve nuclear ignition in the plasma, whereas JET is primarily a device to test scale-up (though it may also achieve ignition). The Garching device would be designed to take account of the radiation hazards.

The proposal is not yet finalised even within Garching, because one of the divisions (high beta plasmas) would have to close. But it is the main contender for Garching's main programme after ASDEX (a device under construction to test the concept of a 'divertor' to clean impurities from the edge of the plasma column). The ignition device would probably be a collaboration between Garching and MIT in the US. The view of the BMFT is not known, but, says a physicist at Garching, "at least they haven't stopped the study".

Another issue which seems sure to come to a head soon lies in a conflict between the basic research funding body DFG and the ministries concerned with a government special programme on 'health research'. Officials at the DFG are worried that criteria used for selecting research for funding under the independent, DM450 million five-year health research programme are too lax. "There is a problem of inflation of poor projects", said one DFG official. "Projects are defined loosely, and so are the assessments". Furthermore the ministries reserve the right to ignore the advice of the scientists they appoint to do the assessments, so that poor research can be funded purely on political grounds.

More recently the DFG has been asked to set up a committee to advise the government on cancer research. It may well be in that committee that the issue will be raised. ☐

US at sixes and sevens over Soviet exchanges

LAST week, Dr Frank Press, the US presidential adviser on science, left for Moscow to discuss the progress of US-Soviet scientific cooperation.

The visit, as part of the regular programme of scientific cooperation inaugurated by the Nixon-Brezhnev agreement of 1974, was originally scheduled for last summer. It was cancelled at the last minute by President Carter in protest at the trial and conviction of Dr Yurii Orlov, the physicist, for human rights activities.

The Soviet science planners clearly welcome the restoration of full scientific relations with the US. Writing in *Izvestiya,* Dr Gvishiani, Deputy Chairman of the State Committee for Science and Technology stressed the "mutual benefit" of such exchanges and answered Western attempts to impede them. He maintained that technology transfer was not as is frequently alleged, a "one way flow"; several US firms, he said, were benefiting from Soviet technology.

At present, except for a few hardliners, there is little support among Western scientists for out-and-out boycott of the Soviet Union. Most would prefer to avail themselves of the opportunities provided by conferences in the Soviet Union to visit those of their colleagues who are dissidents and refusniks.

During 1978, however, some US academics claimed that the State Department and other relevant departments and agencies of the US government appeared to be implementing a policy of discouraging US scientists, who were visiting the Soviet Union as part of the official exchange programme, from contacting dissidents and refusniks.

It appears that pressure ranged from "friendly warnings" to the dismissal of certain known friends of the Soviet "opposition" from honorary but prestigious US government consultancies.

At the end of last year, the Committee for Concerned Scientists Inc., one of the most active human rights pressure groups, made representations to the State Department that this practice should cease. The committee was assured that no such policy in fact existed; if any such actions had been taken, it was on the mistaken initiative of individuals.

One result of the confusion of official US policy on the matter is that, on occasion, the Soviet hosts have been able to exert pressure on visiting scientists to stay away from opposition circles. In one case, a party of scientists was informed by the head of the Soviet welcoming committee that he had an "agreement" with the head of the US exchange programme in physics that scientists on official exchanges should not visit the Sunday seminar for refusniks. Challenged on the matter, the US official in question denied the existence of any such "agreement", as did also the National Academy of Sciences and the various government agencies in charge of exchanges.

If the idea of general boycott is abandoned, scientists concerned about human rights issues could take action by "working to rule" on the vexed question of substitutes. For many years Soviet delegates invited to attend conferences outside the USSR have been replaced by scientific nonentities. Originally, this resulted in free periods in the time-table, but gradually over the years it has become increasingly common for the substitutes to be accommodated in the programme.

Last summer, at the Paris conference on luminescence, a special "Round Table" on the Orlov case was held, and the possibility of a campaign against substitutes discussed. The consensus of opinion, however, was that it would cause too many practical difficulties, and possibly lead to Soviet withdrawals.

So far, only a few hard-liners, such as Nobel Laureate Paul Flery and his four co-protesters, who refused to attend the IFPAC seminar on Macromolecular chemistry in Tashkent, are prepared to make a stand on the "substitutes" issue.

However, a disturbing document issued recently by the Committee of Concerned Scientists may well make it necessary to reappraise the whole problem of substitutes. The report, alleging wide-spread anti-Semitism in Soviet mathematics, stresses that it is virtually impossible for Soviet Jewish mathematicians to travel abroad to conferences. This, it must be stressed, is not a matter of Jews who wish to emigrate to Israel, but simply of Soviet citizens with no "Zionist" inclinations who have a Jewish name and the entry "Jew" on their internal passport.

The Committee for Concerned Scientists strongly urge a "no-substitutes" policy as the best way of helping in such cases. Other countries of the Comecon bloc are, in the main, somewhat more lenient about foreign travel —with the notable exception of conferences held in Israel, which, since 1967, has had no diplomatic relations with any Comecon country except Romania. Poland is perhaps the most lenient of the Comecon countries. A handful of Polish ecologists managed to attend the Intecol-2 conference in Jerusalem last September. However, members of the Polish Biochemical Society are not prepared to rely on this precedent. Already they are making known abroad their wish to attend the meeting of the Federation of European Biochemical Societies in Jerusalem in August, 1980.

It is not sufficient, they stress, that one or two leading Academicians should attend as official delegates— what they are seeking is that any scientist from the Comecon bloc, willing to travel at his own expense, should be permitted to do so.

Moscow's growing pollution problem

INDUSTRIAL pollution in the Moscow region will increase by 150–200% by the end of the century, according to Dr Aleksandr M. Ryabchikov of Moscow State University. Already the city has spread across the ring road originally intended to confine it, and new developments are penetrating into the 'green belt' economy—dairy farming, market gardening, leisure zones and reservoirs, of what is described as the 'second peripheral belt'.

Purification installations are compulsory for all new industrial enterprises, but, according to Dr Ryabchikov, are "insufficiently advanced" and are very expensive, costing up to 40% of the capital cost of the plants. Only the use of abundant non-polluting energy— thermonuclear fusion and solar energy based on photochemistry, he said, can provide a lasting solution to the problem.

Dr Ryabchikov's suggestions follow a broad-based research programme on environmental measures recently been carried out in the geographical faculty at Moscow University.

Sigvard Eklund: the uses and abuses of nuclear energy

• The director-general of the IAEA (above) put the pro-nuclear case in London last week. Judy Redfearn reports

THE increased use of nuclear power has "not contributed to horizontal proliferation and is unlikely to", according to Dr Sigvard Eklund, director-general of the International Atomic Energy Agency (IAEA). At the presidential lecture of the British Institution of Nuclear Engineers in London last week, he supported this claim by saying that only six states have exploded nuclear weapons although many more have the technical know-how to do so.

The political will of states is the key to controlling proliferation, according to Eklund. Without it, international safeguards cannot be effective and "technical examinations are valueless".

Restricting the supply of enriched uranium and nuclear technology to developing countries, as advocated by the United States, is only likely to "encourage nuclear self-sufficiency and therefore increase proliferation", Eklund claims. He suggested the IAEA could work out a scheme to assure countries of essential nuclear supplies. This would have the strength of current non-proliferation arrangements and would assure supplies and safeguards. A disruption in supplies would be a breach of the safeguards. There was a need for urgent action, he said. "Nations would gain more in partnership than in imposing their thoughts on others."

Predictably Eklund is a staunch nuclear supporter. The nostalgia he feels for the time when nuclear engineers were left alone to solve difficult problems "quickly" and impossible ones "with time" illustrates his attitude towards the arguments of the anti-nuclear movement. "Rational arguments", he says, "no longer carry any weight."

Eklund believes that nuclear power will be needed to meet increasing world energy demand. He is sceptical of energy forecasting however: the great variety of estimates of future energy demand are not surprising, he says, considering the many different assumptions energy forecasters have made.

Nevertheless, he believes that the growth in demand will continue over the next decade (though the rate of growth will fall). Even if the developed countries use conservation measures, he says the world demand will continue because of increasing population, economic development, the development of sparsely populated areas (such as Siberia) and the energy needed to recycle increasingly scarce natural resources. "Even if the developed countries have zero energy growth, demand from developing countries will lead to a substantial growth in world energy needs."

Moreover, he says, conservation takes too long to have an effect to be a major factor in reducing energy demand before the end of the century. "Lifestyles and social structures don't change overnight, at least in democratic systems". Neither does he foresee any major role for alternative sources of energy. Those with the greatest potential such as hydroelectric power, he says, are already being exploited and others probably won't have much to offer.

So, in the expectation of increasing demand, Eklund sees nuclear power as ripe for a substantial contribution—at the right stage of development and economically competitive with other energy sources. "I don't believe uranium prices will rise faster than oil prices", he says, and substantial new discoveries of fossil fuels could only postpone the need for nuclear by a few decades. Oil is likely to become increasingly scarce and costly and a rapid expansion in coal production would lead to "serious environmental problems."

Eklund puts a lot of emphasis on fast breeder reactors which, he says, could double the energy potential of uranium and provide the world with abundant energy. Since 1973, however, there has been a drop in the number of FBR projects. "This constituttes a paradox", says Eklund. "Nuclear power has become the victim of the pioneering work on the environment done by its founders." The anti-nuclear movement has become allied to political groups which search for a better 'quality of life'—a term never defined, according to Eklund—rather than a higher 'standard of living'. These groups are not found in totalitarian states, he says: their greatest influence has been in countries with low majority governments such as Sweden and Austria. ☐

Can multinationals aid development?

A RAPID technological transformation, similar to the industrial expansion of Japan in post-war decades, is now facing several developing countries scattered round the globe, according to Dr Jorge Katz, director of the Economic Commission for Latin America's research project on technology and development. Indeed, these nations—which include Brazil, Argentina, Mexico, South Korea, Singapore, and perhaps even India—may soon be in a position to export advanced technical programmes to other countries—although their spread will be on more limited industrial fronts than Japan's.

The slower-developing nations of Central and South America, and also Africa, then become the main targets for industrial and technological exports from their more advanced neighbours. The question then is what these less sophisticated nations will gain in the transaction.

It is generally assumed that developing countries which are used as the sites for the advanced industrial complexes of multinational corporations gain little in the way of technological knowledge of expertise. But Dr Katz challenged this view at a recent symposium at Sussex University, organised by the Science Policy Research Unit there. He maintained that developing nations were able to assimilate information from sophisticated manufacturing plants in their midst.

"You cannot take a piece of technology from a developed country, put it in a developing country and expect it to work in exactly the same way", he said. Altered circumstances often led to changes in plant design and in this way, local engineers and technologists became involved in work that increased their expertise.

However, a variety of economic factors affected the nature of technological transfer gained at plant level. One important determinant was the amount of freedom given by multinational companies to their foreign subsidiaries. For instance, many firms in the United States allowed their subsidiaries to vary original designs, while European, especially Swiss and German, companies tended to forbid this.

Other determinants included the rate of capital subsidy; the rate of exchange; and the cost and variability of local skilled labour. In some parts of Africa, there was practically no skilled labour available. This handicapped the setting up of new factories and in turn prevented new expertise being generated. **Robin McKie**

0028–0836/79/0277—0425$01.00

news in brief

WHO endorses word wide barefoot doctor campaign: The Executive Board of the World Health Organisation has approved a plan for radically improving health care throughout the world by the year 2000. Described as "a landmark in public health history" the plan addresses the failures of present medical establishments to provide satisfactory health care for the great majority of people and proposes the use of appropriate technology, improved nutrition, increased attention to water supplies and the greater use of health auxiliaries, the barefoot doctors pioneered in China.

The WHO proposals stress self reliance and technical cooperation between third world countries. According to a WHO spokesperson the plan calls for a shift away from dependence on transnational drug companies—at present countries spend up to one half of their health budgets on "useless" drugs—and away from reliance on "the great white experts" from Europe and the United States. The board also stressed that good health cannot be separated from economic and social development.

Joint UK-US reactor safety research planned: A joint testing programme on the safety of plutonium fuel will be signed shortly by the UK and the US. The programme will make use of the UK's 250 MW prototype fast reactor at Dounreay and the United States transient reactor test facility (TREAT) located at Idaho Falls, Idaho. Plutonium fuel pins will be burned at Dounreay for varying periods up to their lifetime of two years. After a cooling off period, the pins will be transferred to the TREAT facility where, singly and in bundles, they will be subjected to rapid excess reactivity. This procedure generates rapid temperature changes in the pins and is a way to simulate loss of coolant or control rod malfunction accidents. The pins can then be analysed for structural soundness against this type of accident.

The magazine, *Undercurrents* recently reported that water was found coming out of a 4 inch crack in a primary cooling pipe at the Duane Arnold nuclear reactor in Palo, Iowa. Upon inspection all seven of the cooling pipes were found to be cracked. Two plants of similar design in North Carolina have been shut down for inspection and at least nine others are at risk. A complete break in one of these pipes would cause a major loss of coolant accident of the type that the TREAT facility means to test.

US Congress elects liberals to key science policy committee posts: In a major upset to the traditional seniority system, the US democratic members of Congress have elected liberal candidates to two key subcommittee posts on scientific and environmental issues over the heads of more senior contenders.

Representative Henry Waxman of California, who was only elected to Congress in 1974, has been chosen to succeed Representative Paul Rogers as chairman of the Health and Environment Subcommitee of the House Interstate and Foreign Commerce Committee.

This committee has been the source of much recent health research legislation, as well as of concerted attempts to produce legislation covering recombinant DNA research. Mr Waxman defeated the more senior representative Richardson Preyer, who had aroused certain suspicion through holding financial interests in various pharmaceutical companies, an area of the subcommittee's responsibility.

A further surprise was caused by representative Toby Moffett, another post-Watergate congressman, who was elected to chair the Subcommittee on Environment, Energy and Natural Resources of the House Government Operations Committee.

The two appointments represent victories for labour, consumer and environmentalist interests. However, with a new generation of congressmen arriving in Washington bearing a considerably less liberal outlook than some of their immediate predecessors, few are expecting any radical shift in the activties of etiher subcommittee.

Short term contract researchers meet in Manchester: Research workers from the University of Salford, Manchester University and the University of Manchester Institute of Science and Technology met on 31 January to discuss problems of short term contract workers. Participants discussed individual cases, including that of David Pillinger (25 January, page 255) a tenured cancer researcher made redundant at the Christie Hospital: present deficiencies in the conditions of service of short term contract workers; and long term prospects including a proper career structure and strategies for long term funding including the possibility of prying money out of the University Grants Committee to fund research workers instead of just equipment and buildings as is presently the case. According to convenors Jean Shaoul and Alastair Risk of the University of Salford the questions raised are "fairly standard union matters" but the easy money of the 1960s has spoiled researchers with the result that "present organisation is well behind the rest of the working population." The next meeting is scheduled for 7 March at Manchester University.

Refusnik resists move into secret work: Since he applied to emigrate to Israel in 1974, the position of Professor Solomon Alber, a topologist working at the Institute of Chemical Physics of the Soviet Academy of Sciences has been anomalous. Normally, any such applicant is immediately dismissed from his job; Alber, however, was simply demoted from head of the mathematics department of the institute to a minor academic post. Recently, attempts have been made to shift him to the branch of the institute doing secret work—a ploy which would effectively obviate his chance of ever receiving a visa. Alber is resisting the move. If, however, he fails to comply, the institute will have some basis for his dismissal other than that of his wish to emigrate.

GE researchers develop plan for chemical heat pipe: A research team at General Electric's Research and Development Centre in Schenectady, New York has produced a feasibility study for using industrial waste heat. The study is based on an original German proposal in which heat is used to drive the catalytic conversion (at 1900 °F) of methane to carbon monoxide and hydrogen, $CH_4+H_2O \rightarrow CO+3H_2$. The reaction products are then cooled (the heat being used to warm incoming methane) and are piped over distances up to 300 miles where they are re-combined catalytically in the exothermic reverse reaction, the heat being used locally.

GE scientists sought to find a reaction that would go at the lower temperature of 1000°–1200 °F generated in many types of power station. They found a candidate in the catalytic conversion of cyclohexane to benzene and hydrogen, $C_6H_{12} \rightarrow C_6H_6+3H_2$. The efficiency of the heat conversion and extraction is estimated to be 80% but there are undetermined particle losses in the catalytic reaction. A loss of 1% per cycle would make the proposal unworkable. Research is proceeding to determine this factor.

0028–0836/79/0277—0426$01.00

A modest contribution to security and cooperation

An international science forum is to be held in Hamburg a year from now, in the wake of the signing of the Helsinki Agreement (right) John Ziman, professor of physics, Bristol University, discusses his hopes for the meeting.

TUCKED away among the fifty pages of the Helsinki Agreement is a short paragraph envisaging a 'scientific forum'—"a meeting of leading personalities in science from the participating states". In the two years after Helsinki, this item seems to have been given little attention. But amidst the wrangling at Belgrade last year, it was a relief to agree to set up an innocuous meeting of experts to plan the forum.

This meeting took place in Bonn, during the summer. For six whole weeks, diplomatic and scientific representatives of the 36 signatories of the Final Act of the Conference on Security and Cooperation in Europe (CSCE—alias the Helsinki 'Agreement')—circled warily and delicately around this modest-seeming proposal. Their eventual report was unanimous: the scientific forum will be held in Hamburg, in February 1980.

From the diffuse agenda proposed in this report it is difficult to estimate the significance of the forum. Two weeks of discussions of "interrelated problems of common interest concerning current and future developments in science" are not likely to throw much new light on the human condition, especially when dispersed over such a diversity of topics as "alternative energy sources", "food production", "trends in medical research, in particular in basic research and primarily on cardiovascular, tumour and virus diseases, taking into consideration the influence of the changing environment on human health", and "comparative studies on social, socio-economic and cultural phenomena, especially the problems of human environment and urban development".

In the diplomatic bargaining that produced this list, it was obviously easier to achieve a consensus by including the favourite topic of every delegation than to spend another six weeks trimming it down to size. Thousands of man-weeks of serious discussion of all these topics is already taking place each year, uninhibitedly across all the frontiers of the world; nobody is under any illusions that the forum can do much more scientifically than skim lightly over very familiar ground.

The original text of the CSCE Final Act intends that the forum should "promote the expansion of contacts, communications and the exchange of information, between scientific institutions and among scientists". But here again, a meeting of this kind can do little to supplement the existing network of bilateral and multilateral agreements, involving national scientific organisations, transnational scientific unions, and international agencies, under which such activities already take place on a very large scale. In this respect, the further implementation of the Helsinki Agreement to improve cultural and scientific contacts depends essentially on the amelioration of the general political climate and on detailed attention to a multitude of small obstacles to free traffic in ideas and people.

Nevertheless, those of us who took part in the Bonn meeting came to appreciate the value of the proposed forum as a symbol of the Helsinki spirit, with a modest potentiality for good, both for the progress of science and for the welfare of the people of Europe. In the acrimonious aftermath of Belgrade, it was natural that the proceedings at Bonn were ponderous, and the agreed agenda turned out to be rather trite. This was a diplomatic meeting, with all the rigmaroles of achieving complete agreement amongst the representatives of sovereign states.

If the scientists had been left alone to plan the forum, they might not have been quite so sensitive to the protocols of arriving at consensual proposals within the interlacing alliances of the 'nine' (the EEC) and the 'fifteen' (NATO). Even where there is sharp conflict of interest, as between the countries of the Soviet bloc and the Western democracies, scientific leaders can usually rely upon the shared experiences and common goals of research, so that negotiations of this kind are seldom conducted at arm's length.

But behind the courteously meandering debates and apparently trivial verbal amendments of text lay real issues, which might well have been compromised in a less self-conscious bargaining process. What is science? Is it the technological arm of state power, or does it transcend national frontiers? Should those 'leading scientific experts' who are to participate so gravely in the forum be cast as official representatives of their respective governments, or should they appear as individuals supported by the authority of their scholarly achievements? Are the topics to be treated largely from the aspect of practical application—hence within all the constraints of economic, political and military competition—or in those fundamental aspects that are universal and free for all mankind? These questions were a constant preoccupation of the diplomatic and scientific representatives at Bonn, on both sides of the Great Divide.

On the whole, the agenda of the forum leaves the door as open for truth as for the manifestations of power. This is something of an achievement. From the beginning, the Soviet government and its closest allies were fearful that the West might be tempted to use the forum as an instrument of protest against the oppression of dissidents. Their desire to impose official representative status on the speakers at the forum was as much an attempt to muzzle such 'undiplomatic' mouthpieces as a reflection of their own heavily bureaucratised and subservient scientific systems. The Bonn report does not impose such a gag, thus effectively recognising the universality of the voice of science.

In my view, it would be a mistake for Western scientists to press the human rights issue at the forum. This I say reluctantly, for this issue is profound within modern science. But what is offered at Hamburg, in little more than a year's time, is the opportunity to celebrate, under official governmental auspices, as publicly and as explicitly as could be, the genuinely transnational character of the scientific enterprise. It will be an occasion to demonstrate the universality of empirical fact and rational argument, the communal spirit that pervades research work in all fields, the fraternity and cosmopolitanism of the republic of learning, and the humane benefits that accrue from a body of reliable scientific knowledge. These are the norms to which we refer, these are the ideology of science itself—the ideology to which the dissidents themselves appeal in their opposition to tyranny.

The Helsinki Agreement was about cooperation and détente. The true meaning of these unhappily tattered concepts in the scientific and cultural domain must not be forgotten. The value of the scientific forum is unlikely to be found in deeper understanding of technical scientific issues, nor in another confrontation on socio-political fundamentals, but perhaps in a modest affirmation that truth itself is one of the powers to be reckoned with in the real world. ☐

Causes of cancer

Sir,—In a recent book review I stated that "many, and perhaps most, cancers are caused by certain sexual habits, smoking habits, and gross aspects of diet rather than contaminants" (27 July, page 404). My statement runs counter to the general belief that we are currently suffering an epidemic of cancer due to a multitude of carcinogenic pollutants, and I have been asked, both courteously in private correspondence and sarcastically by Ralph Chernoff (7 September, page 8) to substantiate it. Chiefly, those who are surprised by this statement should read the relevant reviews of cancer epidemiology (*Nature* **265**, 589; 1978) or of cancer trends, but some relevant points can be summarised briefly.

The major age-specific trends over the past decades are not in general upwards, with the notable exception of those cancers associated with cigarette smoking. The American Cancer Society (*A Journal for Clinicians*, **28**, (1), 20–21; 1978) have illustrated this for America, and Doll (*Proc. Roy. Soc.*, in press) has shown it in more detail for Britain, avoiding the older age groups where the progressive elimination of mis-diagnosis produces artefactual trends. Any balanced perspective on cancer must begin with the role of smoking, not with any other aspect of the modern world. (The arguments recently advanced by the office of OSHA in the US that 20–40% of all cancer will soon be caused by industrial exposure are methodologically unsound, for the particular risks which they discuss are very considerably exaggerated.)

Smoking, particularly of cigarettes, is the chief cause of lung cancer in Britain, and smoking is strongly associated with oral and with oesophageal cancer and also, albeit less strongly, with bladder and with pancreatic cancer. Adding up appropriate proportions of the numbers who die of these cancers, smoking is responsible for about 30% of all British cancer deaths, most of this 30% being accounted for by the solidly established causal relationship betwen smoking and lung cancer.

Sexual habits are the chief known determinant of the risk of cancer of the uterine cervix, a disease which is very much commoner in prostitutes than in nuns and which is commoner among women who have had many sexual partners or who began intercourse at an early age. This disease, however, accounts for only 2% of all British cancer deaths, and although we have accounted for "many" British cancer deaths by smoking, we have not yet accounted for "perhaps most" deaths, and cannot do so unless we can describe likely causes for stomach, breast or colorectal cancer.

Stomach cancer used to be very common in the United States, but over the past forty years the mortality from it has decreased tenfold, so that it is now quite rare. The causes for this are quite obscure, especially since treatment has not materially improved, but since downward trends in stomach cancer are at last also developing in Britain one can hope that whatever (dietary?) aspects of the twentieth, as opposed to the nineteenth, century environment has protected the Americans will also eventually protect us.

In Britain, apart from lung (27% of cancer deaths) and stomach (9%), the two commonest sites are breast (9%) and large intestine (13%), and preventable causes for these definitely exist although they cannot as yet be identified with certainty. Early pregnancy seems to protect against breast cancer, but no practicable other way of producing these protective effects is yet known, so let us turn to diet instead. Among rats that have been pre-treated with certain carcinogens, a moderate dietary increase or decrease of certain components of "fat" will greatly increase or decrease their chances of developing breast or colon cancer. In humans, graphs of the per caput fat consumption in various countries against age-standardised cancer rates have been found to yield very striking positive correlations with fat for female colon cancer (81% correlation), for male colon cancer (85%) and for female breast cancer (89%). These correlations, taken together with the evidence in laboratory animals, make it plausible that some gross aspect of diet is a preventable (since people already differ with respect to it) cause of these cancers.

Of course, one particular person's fatal cancer may have had more than one preventable cause, especially if multistage models for cancer induction are approximately correct (Peto, 1977, *Origins of Human Cancer*, Cold Spring Harbor publications). However, this makes it more, rather than less, plausible that among "sexual habits, smoking habits and gross aspects of diet" (such as the consumption of certain fats or fibres) we shall find at least one preventable cause for many, and perhaps most, of today's fatal cancers.

Yours faithfully,
Richard Peto

Radcliffe Infirmary

World futures

Sir,—I would like to point out some curious omissions in Lord Ashby's review of Freeman's and Jahoda's "World Futures" (9 November, page 144).

Ashby cites with approval the choice of four growth options; he forgets that there are also four decay options, which should not be left out *a priori*, merely on the ground that they are less cheerful than the former.

When Ashby agrees with the "outstanding practical conclusion" from the analysis, namely that the absolutely top priority is to narrow the gap between rich and poor, both within and between nations, and that this can only be done by devoting massive resources to certain problems, he fails to mention two important facts. First, that this narrowing of the gap between rich and poor is exactly what has been happening in Western industrialised countries for the last hundred years; second that the same thing is happening now between nations, without any wilful action at all. Although most poor nations have not become richer, western European countries have become immensely poorer, through the operation of political, economic and social forces, such as displacement of industry, loss of control over resources and the corresponding inflation. If this trend continues, these nations will be fully-fledged members of the Third World within a very short time, and this would of course resolve the problem of their devoting massive resources to aid other countries.

Yours faithfully,
S. V. Vaeck

Ministère des Affaires Economique,
Brussels, Belgium.

Energy forecasts

Sir,—Your correspondent reports Amory Lovins commenting favourably on the predictive power of his tabulation of US Energy Demand Forecasts, (18 January, page 163). My analysis supports the opposite view.

Neglecting Steinhart's forecast for 2050 as outside the boundary, and taking instead the lower CONAES 2010 figure as "beyond the pale" for '78, you will discover that the range between maximum and minimum for each year of forecasts is nearly constant at 60 q. Thus as the year of forecast approaches the target year 2000, so the percentage error on the forecasts increases! Is this knowing more and more of less and less?

Yours faithfully,
J. T. D. Mitchell

Abingdon, Oxfordshire, UK.

ARMS cannot negotiate

Sir,—We were gratified to read Mr Hounsell's letter (18 January, page 171) and his expression of support for ARMS albeit with reservations. Let us allay his fears on one or two points. First, the prime objective of ARMS is to seek to develop and establish career structures for full-time research scientists in biomedical sciences, and who could be better motivated than the scientists themselves to do this. Second, we recognise that we have neither the experience nor the rights to 'negotiate' with employers (in the trade union sense) but we can at least enter into discussions, identify problems and make recommendations to both employers and the unions who aim to represent us. If researchers become diverted from working within a trade union as a result of this, then it can only mean that the unions themselves are failing to fulfil the requirements of these workers.

Yours faithfully,
Arleen Unger

ARMS, Clinical Science Labs.,
Guy's Hospital, London, SE1.

news and views

Synthetic genes for human insulin

from Michael J. Gait

THE synthesis of human insulin by bacterial cells fermented on production scale, a dream of molecular biologists for several years, is rapidly approaching reality with the recent announcement of the expression of synthetic human insulin genes in *E. coli* (Crea *et al. Proc. natn. Acad. Sci. U.S.A.* **75,** 5765; 1978; Goedell *et al. Proc. natn. Acad. Sci. U.S.A.*, in the press).

The dream began early this decade with the discovery that pieces of DNA of different origin could be inserted into a bacterial plasmid or virus (*in vitro* recombination). The chimaeric DNA could be used, for example, to transform *E. coli* and clones containing the desired insert selected. It was not difficult to imagine that one day DNA coding for insulin could be inserted into a bacterium and expressed as mature insulin. The idea was also attractive to pharmaceutical industry, conventional methods of insulin production being hopelessly inadequate for projected future needs.

Recently several giant strides have been taken towards insulin expression in bacteria. First, rat pre-proinsulin mRNA has been reverse transcribed into cDNA and inserted into the plasmid pMB9, which was used to transform *E. coli* cells. In one clone the whole proinsulin coding sequence and part of the N-terminal pre-peptide was present (Ullrich *et al. Science,* **196,** 1313; 1977; see also *News and Views* **268,** 198; 1977). More recently Villa-Komaroff *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **75,** 3727; 1978) inserted cDNA, again made from rat pre-proinsulin mRNA, into the coding sequence for the secreted protein penicillinase located on the plasmid pBR322. After transfection and cloning a fused penicillinase–proinsulin translation product was detected to be secreted from the bacterial cell. Isolation of human pre-proinsulin mRNA is technically difficult and has not yet been accomplished. Fortunately an alternative and potentially much more far-reaching approach is now possible based on the use of chemically synthesised DNA.

As a curtain-raiser K. Itakura *et al.* (*Science* **198,** 1056; 1977) showed that synthetic DNA corresponding to the sequence of the peptide hormone somatostatin could be inserted into the plasmid pBR322, this time into the gene for the secreted protein, β-galactosidase. An extra methionine codon was incorporated at the N-terminus of the somatostatin gene sequence, so that after expression in *E. coli* the secreted, fused, β-galactosidase–somatostatin product could be cleaved at the methionine residue by treatment with cyanogen bromide, liberating somatostatin (which contains no methionine).

The same research group has now described the chemical synthesis of two pieces of DNA corresponding to A and B chains of human insulin (Crea *et al. op. cit.*). Each DNA duplex was separately inserted into the plasmid pBR322 in the same way as for the somatostatin gene. After transformation of *E. coli,* fused β-galactosidase-insulin A in one case and β-galactosidase-insulin B in the other were found to be secreted (Goedell *et al. op. cit.*). Free A and B chains are generated by cyanogen bromide treatment, but so far only A chain has been isolated in reasonably pure form. Nevertheless, yields of insulin chains are about 10 mg per 24 g wet cells, about 10 times higher than for somatostatin.

The aim is to reconstitute mature insulin by association *in vitro* of disulphide bonds between A and B chains (proinsulin *in vivo,* consisting of B chain, a connecting peptide and A chain, folds and forms two disulphide bonds between chains A and B. The connecting peptide is then excised to generate mature insulin). One drawback to synthesis of separate insulin chains is that the achievement of high efficiency of disulphide bond association in the correct orientation is currently disputed amongst specialists. Goedell *et al.* (*op. cit.*) indeed report low yields when impure A and B chains are used and so far have only detected mature insulin by radioimmunoassay. A better approach might be to synthesise the DNA sequence corresponding to proinsulin or an analogue with an easily excisable connecting peptide. Here disulphide bond formation *in vitro* is likely to be much more efficient because A and B chains are already in close proximity. However, chains of a possibly active human gene in *E. coli* would require much more stringent containment under the present guidelines than the P2-EK2 used to clone the chains separately. The safety of this procedure would need to be established before large scale cloning could be considered.

Despite the uncertainty of insulin reconstitution the methodology as it stands must be recognised as a remarkable contribution to molecular biology, at least as important as the pioneering synthesis of RNA genes by H. G. Khorana's group (see Khorana *et al. J. biol. Chem.* **250,** 565; 1976; the synthesis of the tyrosine suppressor tRNA gene has finally been completed (T. Sekiya *et al. J. biol. Chem.*, in the press)). Khorana introduced the technology for joining chemically synthesised oligodeoxyribonucleotides 10–15 units long with the enzyme T4 DNA ligase. Using the specific base-pairing mechanism two such chains could be joined in the presence of a third 'splint' chain. A duplex is formed by simultaneous joining of several chains aligned in this way. Crea *et al.* (*op. cit.*) have used the same enzymatic technology, but the chemical synthesis of the 29 oligonucleotides needed to form the two duplexes has taken only a fraction of the time (in man-years) compared with that required for the tyrosine tRNA gene. This is the result of the use of the developing 'phosphotriester' synthetic technology (compared with Khorana's phosphodiester approach) as well as new rapid purification techniques afforded by high performance liquid chromatography.

Now that synthetic DNA can be prepared on a reasonable time-scale the

Gravitational radiation at last?

from P. C. W. Davies

SCIENTISTS have used astronomy as a proving ground for theories of gravity ever since Newton explained the sizes and shapes of the planetary orbits. In 1915 Einstein proposed a new theory of gravity—general relativity—involving bizarre concepts of geometrically distorted space-time, and in a short while minute corrections to Newton's theory were confirmed by careful observation in the Solar System.

Until recently, no qualitatively new tests of general relativity were made. Then, with the discovery of a weird type of double star in which gravitational fields are thousands of times stronger than in the Solar System, the possibility arose of confirming subtle higher-order relativistic corrections to Newtonian gravity. Known as a binary pulsar, the new object is thought to be a pair of imploded stars in orbit around one another. One star is unidentified, but the companion seems to be a neutron star, an object with the mass of the Sun but shrunk to only a few miles in size, so that its immense gravity causes even atoms to collapse into neutrons under their own weight. Rotating many times a second, this collapsed star emits extremely regular and precise pulses of radio waves (hence the name pulsar) which can be monitored on Earth and used as a built-in clock.

Over the past 4 years astronomers have beeen able to follow the convolutions of the pulsar in its orbital dance around its invisible companion. Because of the enormous gravitational fields in the system, relativistic effects are extremely prominent. For example, a progressive twisting of the elliptical orbit caused by space-time curvature amounts to a huge 4.2 degrees per year, which should be compared with the celebrated 43 s of arc per century suffered by the planet Mercury.

On page 437 of this issue of *Nature*, three astronomers report measurements on the pulsar taken with the giant Arecibo radiotelescope in Puerto Rico. The precision of the observations and the quantity of information encoded in the radio pulses is so high that not only can the mass of the pulsar and its unseen companion be deduced, but an internal consistency check can be made on the general theory of relativity. The masses are much as expected, somewhat less than 1½ solar masses, suggesting that both components are neutron stars, but the more exciting result concerns a small, but vitally significant feature of the orbital motion. The astronomers have found that, over the months, the orbital period of the pulsar (which is less than 8 h) is slowly changing. Although the shift only amounts to about one part in 10^9 per year, it is quite distinct and has far-reaching implications.

The systematic drift is readily explained by Einstein's theory. Just as the motion of electric charges produces electromagnetic waves, such as light and radio waves, so the orbital gymnastics of the binary pulsar should produce gravitational waves. In Einstein's theory these are literally ripples of space-time itself, emanating from the central disturbance, transporting energy away from the star system into space. The energy loss is paid for by a decay of the pulsar's orbit, and it is this which the astronomers seem to have spotted. It is similar to deducing the existence of radio waves by observing the rise in one's electricity bill when the transmitter is switched on. Although indirect, the discovery is nevertheless powerful support for the theory of relativity and is bound to attract a lot of scrutiny. Other theories of gravity exist, some of which also predict gravitational radiation, but in many of these the expected effect is considerably larger than that observed. One point which will receive attention is the fact that the relativistic formula that seems to be confirmed is actually only an approximation. The theory of relativity is mathematically extremely complicated and non-linear, and there is some uncertainty over how accurate the existing approximation really is. There is clearly room for more theoretical work here.

Gravitational waves have long been sought on Earth using metal bars or large crystals as detectors. The principle of these detectors, pioneered by Joseph Weber of the University of Maryland, is to measure a faint ringing sound as the space ripples sweep by. Gravity is so weak that even the strongest bursts of gravitational radiation expected from space will deliver less energy to the bar than would a lighted match held a million miles away. Tremendous advances in technology have been needed to overcome this daunting feebleness, and many physicists, despite some early evidence of success, believe that direct detection of gravity waves here on Earth is still some years away. However, new techniques, and new types of detector such as the laser interferometer, should eventually give birth to the new science of gravitational astronomy, enabling astronomers to look at the binary pulsar and other sources of gravity waves with gravity telescopes.

The last great test of Einstein's general theory of relativity, by Sir Arthur Eddington in 1919, caused a public sensation when it was confirmed that the Sun's gravity bends starlight. The binary pulsar has been the first opportunity for the theory to be tested beyond its first-order corrections to Newtonian gravity, but physicists are treating this latest success with quiet satisfaction. Few seriously doubted the outcome. Nevertheless, it is fitting that the centenary of Einstein's birth should see the confirmation of one of the more intriguing consequences of his work.

P. C. W. Davies is in the Department of Mathematics, King's College, London.

---

particular advantages of its use can be truly appreciated. For there are no tricky mRNA isolations involved, merely a knowledge of the required peptide sequence. Codon choice seems not to be a problem, as both the human insulin duplexes (incorporating codons chosen from those most frequently found in phage MS2) and the rat proinsulin cDNA have been expressed in *E. coli*. In the future other peptides and proteins may well be prepared in this way. The DNA sequence need only be synthesised once, Nature's own peptide synthesis mechanism being useable *ad infinitum* (with careful checks for the absence of spontaneous mutations). Moreover, it would be relatively simple to incorporate changes in the amino acid sequences of a protein (by altering the DNA sequence) that might in turn alter its biological activity.

Whereas synthesis of complete genes still requires a substantial investment of finance and personnel, there are several areas of molecular biology where the availability of short, sequence-specific oligodeoxyribonucleotides has made considerable impact recently. Particularly noteworthy is the use by C. A. Hutchinson *et al.* (*J. biol. Chem.* **253,** 6551; 1978) of a 13-mer

0028-0836/79/0277—0430$01.00

complementary to part of the phage φX174 sequence in all but one nucleotide corresponding to the position of the *am*3 mutant. The oligonucleotide was incorporated into a complete, circular, complementary strand, when used as a primer on wild type DNA, with the deliberate G–T mismatch causing an amber mutation in the newly synthesised strand. The use of mismatched oligonucleotide primers could in principle also be used to induce transversions, insertions and deletions, and it is likely that site-specific mutagenesis by this and other techniques will be an area of great future activity.

Synthetic oligodeoxyribonucleotides have also found increasing use in the analysis of DNA structure and function. This topic has been recently reviewed by R. Wu *et al.* (*Prog. Nucleic Acids Res. molec. Biol.* **21**, 101; 1978) and includes applications to DNA sequence analysis, the study of protein–DNA interactions, and the use of oligonucleotides as probes for genes and as tools for molecular cloning of DNA. Indeed the recent dramatic increase in the demand for synthetic DNA has only been partially met by the introduction of more rapid synthetic methodologies. Until commercial enterprise can meet this phenomenal demand some sort of DNA synthesis facility is now an important asset to laboratories involved in molecular biology. ☐

Moscow revisited—laser fusion 1979

from Ian Spalding

It is eight years since the European Conference on Laser Interaction with Matter (ECLIM) was last held in Moscow. At that time only a handful of visitors from the West contributed to an otherwise well-attended conference; the practical importance for laser fusion of creating highly compressed DT targets (with densities much exceeding those normal in the solid state) was becoming increasingly stressed in the published literature, but the available laser technology was still relatively primitive. As a particular example, the energy then available from a state-of-the-art pulsed CO$_2$ laser was only 10 J, with a peak power of ~10 MW! Of comparable importance, the absorption coefficient for radiation of wavelength λ between $\frac{1}{2}$ and 10 μm as a function of incident angle, polarisation and intensity, and as a function of plasma composition and initial distribution, had not been characterised in systematic experiments—nor were the existing measurements well coordinated with available theoretical (mostly analytic) models of relevant linear and non-linear interactions. Although no fundamental break-through was reported at the twelfth conference in the series held recently*, overall progress in the field has been significant and encouraging.

Advances in laser technology over the past eight years have been particularly striking. 10 kJ, 27 TW, Nd : glass and 10 kJ, 20 TW, CO$_2$ laser systems have been successfully commissioned in the past year at the Lawrence Livermore and Los Alamos Scientific Laboratories respectively; all of the 1 μm and approximately a quarter of the 10 μm power has already been symmetrically focused onto gas-filled microballoon 'exploding pusher' targets. DT neutron yield increases with incident Nd laser power to an (unoptimised) 3×10^{10} neutrons at 27 TW; scaling at both wavelengths fits quasi-analytic models. Significant thermonuclear burn will however require the experimental achievement of an isentropic compression of the target's core, so more complex layered microballoon 'ablative burn' targets are now receiving increasing experimental attention. At incident powers $<10^{12}$ W, the KMS and KALMAR (Lebedev) Nd lasers have demonstrated compressions approaching × 35 (hydrogenic) solid-state densities, using cryogenic targets and α-emission spectroscopy KMS claim that this compression is partly adiabatic. In summary, available 'driver' powers have increased tremendously over the past eight years—for CO$_2$ lasers by a factor of 10^6; ideas advanced for larger systems (regenerative relayed amplifiers, stimulated Raman/Brillouin convertors and so on) suggest that 0.1~1 MJ drivers (predicted to be of practical interest) may well be operational within the next decade.

Developments in the understanding of laser–plasma interactions, and of the necessary diagnostic techniques, are equally impressive. Various groups have experimentally investigated the absorption of laser light at wavelengths λ of $\frac{1}{4}$, $\frac{1}{2}$, 1 and 10 μm, and at intensities I within at least part of the range $I=10^{10}-10^{16}$ W cm^{-2}; there now seems to be universal agreement that strong density-profile modifications are induced by radiation pressure effects when $(I\lambda^2)\sim10^{15}$ (W cm^{-2}) μm^{-2}, and that resonance absorption significantly increases the total absorption coefficient at the longer wavelengths. Related measurements suggest that much of the absorbed radiant energy is then converted to hot, non-thermal, electrons. Developments in two and three-dimensional soliton theory, and in analytic modelling of strong turbulence by the Russian school, are equally impressive. The main topic for controversy appears to be the computer optimisation of target designs, where the avoidance of unwanted core preheating by the 'hot' electrons and of possible deviations from the desired symmetry of implosion (due to Rayleigh-Taylor instabilities) poses significant modelling problems in the hydrodynamic codes. The US prefer 'thick' (lower aspect ratio) double-shell designs to obviate both of these problems. The increasing tendency of American and Russian theoreticians to 'cross-calibrate' predictions from their codes against published experimental work seems therefore a noteworthy and potentially fruitful development.

It is particularly interesting that Academician E. P. Velikhov took the opportunity of a round-table discussion (including proponents of electron-beam fusion and fission/fusion hybrids) to suggest that the time was ripe for a cooperative international venture in laser fusion, perhaps under the auspices of the IAEA. In making this personal suggestion, he cited the recent IAEA decision to initiate the Intor (joint-Tokamak) study as a bold and historic venture. ☐

I. J. Spalding is in the Experimental Division A, UKAEA, Culham Laboratory.

*ECLIM XII was held in Moscow's Polytechnic Museum on 11–15 December, 1978.

Variations on a theme

from Peter Newmark

Without their analogues, synthetic or natural, insulin experimenters would soon be on the streets. Fortunately the chemist's ingenuity keeps ahead of the biologist's appetite for quantity and variety. For it is through the application of old and new analogues that those attending a recent meeting* saw the eventual solution to most of the mystery still surrounding the actions of insulin.

How exactly, for example, does insulin bind to its cell surface receptor? The combined powers of crystallography and analogue study have outlined the domain on the surface of the insulin which is implicated in binding—a domain which has never been so clear as in the computer-generated molecule presented by P. de Meyts (ICP, Brussels) and R. A. Feldman (National Institutes of Health, Bethesda). (This film was not just a

---

*A European Workshop on Insulin Structure organised at the ICP, Brussels, 13–15 December, 1978 by P. De Meyts and D. Brandenburg.

0028–0836/79/0277—0431$01.00

remarkable travelogue around the surface of insulin but, since its images are generated from molecular X-ray coordinates it heralds a more accurate and far easier method of 'building' models than is now possible). Although the binding domain has been identified, the specific role and importance of individual amino acids within the domain remain uncertain. Certainty may come from new analogues. Perhaps the chemists will succeed in modifying one of the implicated amino acids in a minor way but with drastic consequences for binding. Or perhaps the isolation of a natural insulin analogue from some exotic species will spare the chemist's toils.

It would also help if the receptor for insulin were available in purified form. But that, according to L. Kuehn (Dusseldorf University), will require either a method of affinity chromatography better than any now available, or an alternative, non-classical approach. Matters may be helped by the availability from the laboratory of D. Brandenburg (Deutsches Wollforschungsinstitut, Aachen) of photoaffinity insulin probes for the receptor, which are now being put to use.

Another very recent Aachen contribution is a series of covalent dimer insulins, potentially useful probes of the subunit structure of the receptor. Several varieties of covalent linkage are possible and A. Schuttler described their preparation from insulin molecules with protected end groups.

Early data from the testing of the dimers in various biological systems have contained enough oddities to arouse even the most jaded analogue addict. In the adipocyte lipogenesis assay, for example, the activity of the dimer in which the linkage is between position 1 of the B chain of one molecule and position 29 of the B chain of the other is only very modestly reduced compared with native insulin (R. Jones & P. Sonksen, St Thomas's Hospital Medical School; Schuttler). Also, and against the usual correlative trend, the activity *in vivo* on blood glucose levels of this dimer was much lower than on lipogenesis *in vitro* and, for the activity observed *in vivo*, the blood clearance rate of the analogue was surprisingly high (Jones & Sonksen).

The crystal structure of insulin is of course well established at high resolution but as T. Blundell (Birkbeck College, London) emphasised, crystalline insulin is in hexamer or dimer form which may not provide a good guide to the structure of the biologically active, soluble monomer. Early indications from a variety of sources suggest that insulin does have flexible surface groups whose structure changes considerably when insulin polymerises contacts. According to Blundell the conformational flexibility seen in the crystalline insulin hexamer is not so evident in its stable-mate, pancreatic polypeptide III, the high resolution structure of which is in the offing.

With an inevitability characteristic of any peptide hormone meeting these days, matters were not complete without the externalisation of internalisation. The most thorough contribution came from J. L. Carpentier (Ecole de Medicine, Geneva). The data he presented showed convincingly that $[^{125}\text{I}]$ insulin was internalised in lymphocytes and hepatocytes and, with time, accumulated in lysosomes and/or Golgi bodies. The 'point' of internalising insulin (and other hormones) remains enigmatic. There is no evidence for a functional role for insulin within the cell despite the somewhat surprising claim by Carpentier that the internalised hormone is largely undegraded and therefore potentially active. It must be recorded however that data from other less thorough studies was not all consistent with internalisation.

Finally J. Gliemann (Copenhagen University) showed that insulin monoiodinated at A14 (tyrosine 14 of the A chain) had twice the affinity of the A19 isomer for the receptor on adipocytes, a factor of such consequence to some experiments that they will bear repeating when the pure A14 isomer is available. Then there is a move to iodinate all analogues and to redetermine their binding parameters by direct instead of indirect means. And there are no end of interesting vertebrates whose insulin has yet to be sequenced—the latest to fall being the casiragua (R. Horuk, Birkbeck College) a rodent relative of the coypu and guinea pig. And still to be answered categorically is the question of whether invertebrates have insulin or some forerunner molecule.

Insulin experimenters, the world is your oyster. Oysters, does your world have insulin? ☐

The world's vanishing primates

from Michael Kavanagh

THE International Primatological Society this year held its Congress in Bangalore, India and in one of the satellite symposia* attention was focused on the enormous problems facing primate conservationists in neighbouring Bangladesh. The forests that are the natural home of the country's monkeys and apes are now almost entirely restricted to three areas in the centre and south of the country and they are being destroyed at an alarming rate. None is totally protected and whereas the government estimates Bangladesh's forest area at about 8,600 square miles, this figure is reduced to less than 3,000 square miles when timber monocultures, tea estates, rubber plantations, grasslands, scrub and other man-made vegetation types are excluded. 'Common' langurs (*Presbytis entellus*) seem to be extinct and there are estimated to be only about 35,500 of the most abundant primate, the rhesus monkey (*Macaca mulatta*), left in the forests. A few more survive in the towns, but in contrast to India where wildlife is generally revered, Bangladesh is a country in which most people are ignorant about wild animals and regard them as dangerous or destructive objects to be killed or persecuted in any way possible. In describing his country's situation, Ali Reza Khan stressed habitat destruction and the lack of education about the natural heritage as the two major threats to primate conservation. Habitat destruction results from the needs of a human population that has reached an average density of 3,000 per square mile of land; and as far as education is concerned, Reza Khan reported that international help is desperately required for such basics as buying the books that Bangladesh cannot afford. He illustrated the Bengali attitude to wildlife with the story of a serow (*Capricornis sumatraensis*), a large, long-legged goat antelope, that wandered over the border from India. It was chased by a mob of thousands of people who attacked it with sticks and stones. Eventually the police intervened and took the animal into protective custody in the local jail until they could hand it over to the Forestry Department.

In describing the plight of Bangladesh's primates and in calling for a moratorium on all exports at least until the primate populations have been thoroughly surveyed (a task in which he is involved), Reza Khan reflected the major concern that dominated the congress. Although the society is an academic body, no academic issue caught the minds of large numbers of

delegates in the way that was true of conservation.

Inaugurating the congress, V. Ramalingaswami, President of the Indian National Science Academy, stated that half of the world's 180 non-human primate species were in danger of extinction and he called for a deeper understanding of primate biology in order to facilitate management for survival. He urged biomedical researchers only to use primate subjects where absolutely necessary and pointed out their common interest with conservationists in that both groups desire the preservation of primate populations.

A Conservation Round Table, which was intended to last for a morning, continued by demand of the participants throughout the afternoon with delegates offering summaries of the situation in almost every country that has indigenous primates. In summing up this session in his report to the Business Meeting of the Society, Vice-president J. S. Gartlan struck several themes. First, education about conservation appears to be a major need throughout much of the world. Where efforts have been made, the results have been encouraging. A case in point is Kenya, where the Wildlife Clubs are working successfully in schools. At a higher level, there is a need for the education of field staff (such as game rangers) in the developing countries. This must go hand in hand with the provision of incentives in terms of jobs and security.

Second, the greatest threat to natural primate populations comes from habitat destruction, with trade and hunting for any purpose being of variable seriousness in different areas. He contrasted India where wild animals are seldom molested with West Africa where hunting for protein is a major problem.

Third, the outlook in any area can change rapidly, often due to government action. For example, Guyana still contains large areas of relatively undisturbed forest in its interior, but the government has declared its intention to develop this land for human use including that of providing a site for a new national capital. Gartlan urged continual surveillance of parks and reserves to guard against encroachments or changes in their legal status.

Fourth, management of the ecosytem is essential for a conserved area, and therefore any plans to create a national park or a reserve are worthless without such management.

Gartlan's fifth theme reflected the activist mood of the delegates. He pointed out that most wild primate populations are to be found in tropical countries where much development is funded through international agencies. He suggested that modification of plans at an early stage could often be of benefit to primate conservation and that therefore the International Primatological Society should develop an

The primates of peninsular Malaysia

from David Chivers

The evergreen rain-forest that covers nearly half the land area of Peninsular Malaysia is rich in primates and other wildlife. There are three species of lesser ape, the siamang (*Hylobates syndactylus*) and lar gibbon (*H. lar*) with the agile gibbon (*H. agilis*) in the north, two species of macaque, the long-tailed macaque (*Macaca fascicularis*) and the pig-tailed macaque (*M. nemestrina*), two species of leaf monkey, the dusky leaf monkey (*Presbytis obscura*) and the banded leaf monkey (*P. melalophos*), (with a third species, the silver leaf monkey (*P. cristata*) in the mangrove swamps of the west coast), and the prosimian slow loris (*Nycticebus coucang*).

Habitat varies with altitude; the lowland Dipterocarp rain-forest has the most varied flora and fauna, and primates abound. The gibbons and leaf monkeys extend up into hill Dipterocarp forest and sub-montane formations, but the smaller gibbons and dusky leaf monkey are more restricted to the lower forests. Pig-tailed macaques show a preference for the higher, more remote forests, while the long-tailed macaques prefer riverine forest and disturbed habitats, in which they scavenge on the by-products of human society.

Forest clearance poses the main treat to Malaysia's wildlife; timber is a valuable resource which has been over-exploited. There is increasing realisation that such benefits are short term, with possible disaster beyond. The maintenance of permanent forest reserve over about 45% of the Peninsula will, it is hoped, contain the increasing problems of flooding and soil erosion. The long-term economic benefit of sustained, light, selective logging, harvesting of other plant products, and cropping of various mammal species in such managed forests, and the benefits of protecting watersheds and organising tourism in undisturbed habitats remain to be established. This needs to be coupled with the more efficient use of agricultural areas.

Until this long-term equilibrium between man and wildlife is established there is the distressing problem of wildlife made homeless by clear-felling. Unless animals can be transferred to other forests where numbers have been reduced by hunting, they are doomed. The Wildlife Department have shown their interest in tackling this problem, and current research projects will, one hopes, provide guidance.

The Game Department in Malaysia has been reorganised into the Department of Wildlife and National Parks, with the Chief Game Warden, Encik Mohamed Khan bin Momin Khan, KMN, as its Director-General; numerous research officers have been appointed, and a generous allocation of government funds has been made for conservation in the current quinquennium under the Third Malaysia Plan. Apart from coordinating the conservation effort, with encouragement from the Malayan Nature Society, the department is also responsible to the Ministry of Science, Technology and Environment for maintaining national parks and game reserves and enforcing the rigorous laws that protect Malaysia's wildlife. Only *M. fascicularis* is exported at present, at a rate of less than 10,000 a year. More information is needed urgently to assess the effect of this on the wild population, whether the export of any other species can be justified for essential medical research and, if so, in what numbers.

It is against this background that a 3-year programme of collaborative research between Universiti Pertanian Malaysia, Universiti Kebangsaan Malaysia and the University of Cambridge was started in July 1978, assisted with funds from the US Public Health Service, the L. S. B. Leakey Foundation and The Royal Society. The main aims are to study the socio-ecology of the lesser-known species such as the slow loris and the pig-tailed macaque, and to assess the distribution and habitat preferences of each species throughout the peninsula. The intention is to determine precisely the effects of different degrees and types of habitat disturbance on primate populations. Laboratory studies on many aspects of the biology of the indigenous primates will be made using animals displaced by forest clearance. These studies should provide the information essential for their conservation in both natural and disturbed habitats.

David Chivers is in the Sub-Department of Veterinary Anatomy, University of Cambridge.

0028–0836/79/0277—0433$01.00

early warning system by monitoring international agency intentions. The possibility would then be open for members in areas to be affected to comment constructively to the benefit of conservation requirements.

Finally, he pointed out the failure of many countries to sign the Washington Convention on International Trade in Endangered Species. Austria, Italy and Belgium have not signed, and as a result Europe is a major centre for the smuggling of endangered primates. Similarly, Japan has failed to sign and, according to Gartlan, is a major market for endangered species.

Many delegates volunteered to participate in a network of primatologists who may be called on for a coordinated letter-writing campaign whenever a conservation crisis threatens. The hope is that evidence of worldwide concern will persuade national agencies to modify development plans that threaten primate populations. In my experience, conservation is always a major issue at meetings of the International Primatological Society, but never before has there been such a general sense of urgency. ☐

Compensation of Doppler-broadening using light shifts

from Peter Knight

A NOVEL technique has been developed by Cohen-Tannoudji and his colleagues at the Ecole Normale Supérieure and Collège de France to produce Doppler-free optical emission with highly anisotropic spectral properties. Normally a cell of excited atoms in random motion will produce an optical field by spontaneous emission whose spectrum is isotropic: no matter which end you look at with a spectrometer, the radiation will be seen to be broadened by Doppler effects to a width typically many times larger than the natural single-atom width. Cohen-Tannoudji has found ways to pump a cell of atoms in random motion with an intense laser field so that the atom can emit (or absorb) radiation without Doppler broadening. The radiation from such pumped atoms is Doppler-free in the forward direction with respect to the laser field with a width governed by the homogenous (natural and collisional) lifetime. In the backward direction the radiation is broadened in excess of the Doppler-width. The process operates by compensating for the Doppler velocity-dependent of transition frequencies by shifting and splitting the atomic levels in a balancing velocity-dependent manner by interaction with a saturating laser field on a connecting laser transition sharing a common lower level (Fig. 1).

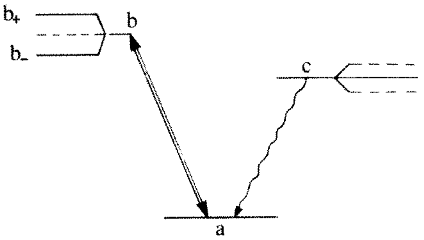

Fig. 1 Energy level scheme for Doppler broadening compensation by light shift perturbations. Levels b and c are Zeeman split by a magnetic field. A circularly polarised laser excites the ab$\pm$ transitions and the linearly-polarised emission from c_0 to a is detected.

Cohen-Tannoudji's first proposal, made at a symposium on frequency standards in 1976, required the use of two saturating laser fields. An optical field detuned by an amount α from a transition frequency of an atom at rest in the laboratory will shift the transition frequency to a new intensity-dependent 'dressed' frequency by a dynamic Stark shift (*Nature* **265,** 683; 1977) which has a dispersion shape. A second laser field detuned an amount α in the opposite direction will produce an equal and opposite Stark shift. The frequency pushing balances the pulling, and for this zero-velocity atom there is no intensity-dependent dynamic Stark shift, or 'light shift'. For an atom with non-zero velocity, then in the atomic rest frame the atom is illuminated by two laser fields with unequal detuning, and the light shifts do not balance out to zero. The laser perturbation of transition frequencies is velocity-dependent, and a careful choice of intensity could counteract the Doppler shift of emission lines.

Together with Hoffbeck and Reynaud, Cohen-Tannoudji (*Opt. Comm.* **27,** 71; 1978) has discussed how the same effect can be produced using one saturating laser field interacting resonantly with two symmetrically detuned atomic transitions separated by a Zeeman splitting (Fig. 1). In Fig. 1, a circularly polarised laser at frequency ω excites the ab_+ and ab_- transitions which have frequencies $\omega+\delta$ and $\omega-\delta$ where δ is the Zeeman splitting caused by a magnetic field. Each of the transitions light-shifts the level a (and b$\pm$). Again for an atom at rest in the laboratory with $v=0$ these light-shifts cancel, but for $v\neq0$ the atomic transition frequencies are intensity-dependent and velocity-dependent in a way that can balance the Doppler shift of emitted lines. For example if the atom sketched in Fig. 1 were weakly excited by a discharge so that radiation were emitted in decaying from another level (way out of resonance with the pump laser on the ab line) c_0 down to a, the emitted light would be Doppler-shifted by a factor $(1-v/c)$ in the forward direction. But if the energy level a were to be light-shifted in a velocity-dependent way as explained, this could shift the ac_0 transition frequency to compensate for the Doppler shift in the forward direction. If this can be arranged for a large enough fraction of the atoms with a spread of velocities, then a significant proportion of the ac_0 transition radiation will be Doppler-free and hence narrowband. Conversely, in the reverse direction the Doppler shift factor is $(1+v/c)$ and the light shift reinforces the Doppler shift, broadening the line to perhaps even double the conventional Doppler width. The special profile of the radiation produced by this 'dressed' three-level system is highly anisotropic. Cohen-Tannoudji *et al.* have determined analytical criteria for Doppler-compensation and discuss the spectra of the emitted light and the way in which the intensity-dependent dressing interactions modify the spectrum of the emitted radiation in the forward direction and produce dynamic-Stark split satellite lines (which they neatly explain in terms of inverse Raman scattering).

Two distinct cases are discussed: partial Doppler compensation for modest laser intensities, where three narrow structures are predicted, and full Doppler compensation for more intense fields where the spectral profile contains a sharp Doppler-free central component and two small Doppler-broadened sidebands. An interesting feature is that the narrowing is entirely due to the energy perturbation of the final state of the transition. The width of the narrow line is governed by parameters such as natural lifetime and collision rates and does not exhibit power-broadening even at high intensities. Other early work on the cancellation of Doppler shifts by a light shift almost linearly dependent on the atomic velocity was reported by Toschek at the 1975 Les Houches meeting (*Frontiers in Laser Spectroscopy* **1,** 329, North Holland, 1977).

Experimental work in progress at ENS using dye laser excitation of ^{20}Ne at 6,163 Å in a magnetic field (to produce the two oppositely detuned Zeeman transitions) and monitoring emission from the third level (c_0 in Fig. 1) has observed the partial Doppler compensation. The emission features in zero magnetic field (a doublet pro-

0028–0836/79/0277—0434$01.00

duced by the dynamic-Stark splitting of level a by the dye laser field) develops a narrow central feature as the magnetic field is increased, as predicted by Cohen-Tannoudji *et al.* The work has novel implications for Doppler-free superradiance, the observation of Doppler-free coherent transients, and predicts striking forward-backward asymmetries in spectral profiles of great interest in intracavity ring systems. □

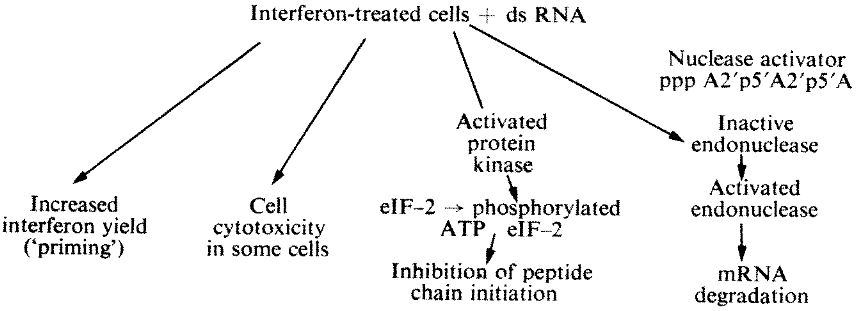
Interferon and double-stranded RNA

from John Morser and Derek Burke

THE *pas de deux* between interferon and double-stranded RNA (dsRNA) continues (see *News and Views* **273,** 97; 1978). It has been known for many years that treatment of cells with double-stranded RNA induces interferon. It now seems likely that viruses also induce interferon by virtue of their ability to make double-stranded RNA, as shown by the elegant study of Marcus and Sekellick (*Nature* **266,** 815; 1977), although additional factors might also be involved (see Kowal & Youngner *Virology* **90,** 90; 1978). When either double-stranded RNAs or viruses are used as inducers, the interferon yield can often be increased by pretreatment of cells with interferon ('priming'). Priming is specific for interferon and it may often turn a non-inducible system into an interferon-producing system. Some cells, notably mouse L cells, also show a pronounced cytotoxicity when treated with interferon and double-stranded RNA (Stewart *et al. Proc. natn. Acad. Sci. U.S.A.* **69,** 1851; 1972). Since such cells also produce interferon, interferon is being synthesised by cells undergoing pronounced cytotoxic damage. Finally, when interferon-treated cells are exposed to double-stranded RNA, translation is blocked, and a series of recent papers (Kerr & Brown *Proc. natn. Acad. Sci. U.S.A.* **75,** 256; 1978; Ball & White *Proc. natn. Acad. Sci. U.S.A.* **75,** 1167; 1978; Lewis *et al. Eur. J. Biochem.* **86,** 497; 1978; Schmidt *et al. FEBS Lett.* **95,** 257; 1978; Farrell *et al. Proc. natn. Acad. Sci. U.S.A.* **75,** 5893; 1978) shows that at least two separate mechanisms are involved. One involves the activation of a protein kinase that phosphorylates, and consequently inactivates the initiation factor eIF-2, and the other involves the formation of pppA2′p5′A2′p5′A ('two-five A') which in turn activates a constitutive inactive endonuclease that degrades mRNA (see diagram).

These effects of interferon require the presence of chromosome 21 in human cells, probably to make the interferon receptor on the cell surface. Both pathways that lead to inhibition of protein synthesis require ATP: the pathway resulting in inhibition of peptide chain initiation for the activation of the protein kinase system, and the one resulting in mRNA degradation to synthesise two-five A by the interferon-induced oligo-isoadenylate synthetase. The scheme reveals a paradox: cells in which protein synthesis has been impaired by two separate mechanisms are also the cells in which interferon mRNA is being actively translated. How can a new protein be formed in such cells? Are any of the intermediates involved in the induction of the interferon gene? The enzyme that synthesises two-five A is possibly one candidate, since it complexes sufficiently well with double-stranded RNA for that to be used as a purification method (Hovanessian *et al. Nature* **268,** 537; 1977), and seems to be present in small amounts in cells which have not yet been exposed to interferon.

One generalisation can be made, however. Interferon sensitises the cell to double-stranded RNA—so that a series of processes which previously occurred either not at all, or at low levels, is now activated. Perhaps this is the control function of interferon—to tell the cells to respond to dsRNA—either added as a synthetic dsRNA (poly (rI)·poly (rC)) or formed as a by-product of virus multiplication.



Interferon-treated cells + ds RNA
Nuclease activator
ppp A2′p5′A2′p5′A
Increased interferon yield ('priming')
Cell cytotoxicity in some cells
Activated protein kinase
eIF-2 → phosphorylated eIF-2
ATP
Inhibition of peptide chain initiation
Inactive endonuclease
Activated endonuclease
mRNA degradation

It is well known that reticulocyte lysates are exquisitely sensitive to the effect of dsRNA, much more sensitive than are cell-free systems made from normal cells and as sensitive as cell-free systems made from interferon-treated cells. Hunt (*News and Views op. cit.*) has suggested that this is because erythrocyte differentiation depends on exposure to interferon at some stage. Certainly interferon antagonises the effect of colony-stimulating factor, inhibits the growth of haemopoetic colony-forming cells and interferes with the normal differentiation of granulocyte–macrophage precursors (McNeil & Fleming in *The Interferon System: a Current Review to 1978,* Texas Reports on Biology & Medicine (eds Baron & Dianzani) 343; 1978). Interferon also inhibits the expression of erythroid differentiation in Friend leukaemia cells treated with dimethylsulphoxide (Rossi *et al. ibid* page 420).

If interferon is involved in any way in differentiation, is this the reason why the interferon system is an inducible rather than a constitutive system and why it is completely uninducible in mouse teratocarcinoma stem cells (Burke *et al. Cell* **13,** 243; 1978)? Perhaps dsRNA is a pleiotropic effector, but only active in interferon-treated cells? We do not yet know the answers to these questions, but perhaps we should look harder for double-stranded RNA elsewhere. □

Radioactive waste management

from S. Weisenburger

THIS interdisciplinary meeting*, covering a broad range of topics, from the processing, solidification, and characterisation to the isolation of radioactive wastes arising from the nuclear fuel cycle was devoted especially to scientific research aspects of radioactive waste management. These aspects have often been relegated to the sidelines in international gatherings chiefly concerned with systems management.

A general review on the management of nuclear waste by Rustum Roy

---

*An International Symposium on 'Science underlying waste management' was held in Boston on 28 November–1 December, 1978 and sponsored by the Materials Research Society. The proceedings will be available in Spring, 1979.

0028–0836/79/0277—0435$01.00

(Pennsylvania State University) ranged from the selection of suitable matrix materials for different types of nuclear wastes to geological considerations relevant to nuclear waste storage.

Several schemes of radioactive waste solidification are currently under consideration. Most papers dealt with matrix materials for high-level radioactive waste (HLW). The technologically most advanced solidification process for HLW is vitrification, which is already in use (for example the French AVM process). However, there are still very intensive research and development efforts aimed at putting the waste into solid forms other than glass, thus providing even better barriers.

Processes based on multibarrier encapsulation concepts were also presented. An alternative approach is to incorporate the radionuclides into minerals (or a synthetic host simulating a mineral) known to have been stable for millions of years in the past. The fixation of HLW in cermet form with an iron-nickel base was also considered. Multibarrier encapsulation relies on up to three barriers to isolate radionuclides from the environment: a solid waste inner core, an impervious coating and a metal matrix. Two candidate materials for the inner core have been suggested: sintered ceramic and glass marbles. If it were desirable to produce a waste form with enhanced inertnes (compared to monolithic glass) but with minimum technological complexity, then glass marbles encapsulated in a vacuum-cast lead alloy was recommended for further development.

An example of incorporating HLW into minerals is the SYNROC-process which has been developed on a laboratory scale. SYNROC is a synthetic rock composed of phases such as hollandite, cubic zirconia, perovskite and celsian and its bulk composition is characterised by a high content of TiO_2 (35%) and a low content of SiO_2 (12%). Calcined HLW can be added to SYNROC-melts and the mineral assemblage can be formed by direct crystallisation from a melt cooled below 1300 °C, or by hot pressing under subsolidus conditions at 1100–1250 °C. The product is considered to be highly resistant to alteration and leaching in any geological environment. The SYNROC process is far from ready to be put into practice in an engineering sense and some important aspects are not entirely clear.

Many papers dealt with the characteristics of nuclear waste in forms including glass, glass-ceramic, ceramic, minerals, cement, and concrete. Besides microstructural characterisation, the measurements of leach rates and leach mechanism of solid radioactive waste forms were of major concern. Detailed knowledge about leaching is required to establish which are the hazardous radionuclides if and when the waste comes into contact with a leaching medium. The specific radionuclides of concern are relatively few (^{137}Cs, ^{90}Sr, rare earths, actinides). It was shown that the leaching process can be highly complex and that the chemistry of nuclear waste glass reactions must take into account a multitude of diffusing species, as well as changes in the leach interface, and that the solvent chemistry may not remain constant throughout a test run. Expressions were given which fit the leach data and which were based on diffusion models in combination with other influences (time-dependent surface concentration of mobile species, dissolution and precipitation of mobile species, dissolution of matrix material). A relatively new method was described which allows measurements of compositional profiles in the leached waste material using ion beam spectrochemical analysis.

The main subject of the presentations dealing with radioactive waste in geological settings was the detailed analysis of the interaction of waste glass with the geological environment. The most credible scenario for rapid mobilisation of the radionuclides contained in the waste is dissolution due to mobility of indigenous water in the host rock or intrusion of ground water in the repository. The combination of radioactive decay heat (in the first few hundred years) and pressure would then create a 'hydrothermal' environment (up to 400 °C, 300 bar) that may accelerate corrosion and breaching of canisters. Results of experimental work show that the hydrothermally reacted glass forms complex produces. Under the applied experimental conditions the glass tends to convert to a substantial extent into crystalline phases (50%), the major component being $NaFeSi_2O_6$. Bulk X-ray fluorescence analysis of the surface of the reacted glass had shown that Cs, Rb, and Mo were significantly leached into the aqueous phase. Methods were proposed to protect reactive waste from hydrothermal conditions or to produce waste forms which can withstand such conditions (multibarrier waste isolation shows significant promise).

Thirteen papers dealt with radionuclide transport phenomena in geomedia. There is still a paucity of quantitative estimates of the various geological materials' ability to retard nuclide movement, but progress does appear to have been made in establishing a data bank for sorption and migration of radionuclides in different geological media. These data are urgently needed as part of the input for modelling and safety assessment of geological waste repositories. A number of thermodynamic as well as kinetic parameters influence sorption and migration data and it is now being realised that the numerous experimental designs used for their measurement should be replaced by standard techniques. Any prediction of the long-term sorption and migration behaviour of the radionuclides, must take into account the effects of specific variables such as permeability, porosity, cation exchange capacity, particle size and surface area.

Modelling and safety assessment is mainly concerned with detailed analyses of the full spectrum of phenomena which alone or in consort, could conceivably lead to significant leaching. Results were presented from a pilot computer program based on a model for a geological system containing a waste repository.

To summarise, the symposium showed that extensive scientific research is being done in the field of nuclear waste management. However, it is also clear that much more research and development is required before the behaviour of radioactive waste is fully understood. □

S. Weisenburger is a research staff member of the Nuclear Research Centre, Karlsruhe, Germany.

NATURE

A hundred years ago

WE learn from the *Journal de St. Petersburg* that the epidemic in Astrakan was discussed before the Russian Medical Society at a gathering where 800 were present. It seems that the people call it the plague, though it is not officially so known. M. Botkine mentioned that at the time of the last plague at Moscow in 1770, the question was discussed whether it was the true plague or a marked form of typhus, and he added that the diagnosis of the various forms of typhoid infection in Russia is very difficult. He believes that the spots on the body and the quickness with which death follows indicate that the present epidemic of Vetlianka is not a European malady. Dr. Nicolaïew, describing the symptomatology of the plague, said that its action is both physical and moral, and that to impose quarantine often helps rather than retards the spread of the disease by the fear it awakens.

Measurements of general relativistic effects in the binary pulsar PSR1913+16

J. H. Taylor, L. A. Fowler & P. M. McCulloch*

Department of Physics and Astronomy, University of Massachusetts, Amherst, Massachusetts 01003

Measurements of second- and third-order relativistic effects in the orbit of binary pulsar PSR1913+16 have yielded self-consistent estimates of the masses of the pulsar and its companion, quantitative confirmation of the existence of gravitational radiation at the level predicted by general relativity, and detection of geodetic precession of the pulsar spin axis.

THE earliest observations of binary pulsar PSR1913+16 showed that, because its orbit involved large velocities ($v/c \approx 10^{-3}$), a high eccentricity ($e \approx 0.617$), and relatively strong gravitational fields ($GM/c^2r \approx 10^{-6}$), several special and general relativistic effects should eventually be observable[1]. The advance of periastron (at the rate $\dot{\omega} \approx 4.2$ deg yr^{-1}) was the first of these effects to be measured[2], and the rate of advance has now been determined to better than 0.1% accuracy[3,4]. We report here the detection of four more effects of relativistic origin, including quantitative measurements of three of them. Together with the much larger effects already measured, the new parameters over-determine the system and provide: (1) the first determination of the mass of a radio frequency pulsar; (2) constraints on the nature of the companion star, and a measurement of its mass; (3) determination of the angle of inclination between the plane of the orbit and the plane of the sky; (4) quantitative confirmation of the existence of gravitational radiation at the level predicted by general relativity; and (5) qualitative observation of geodetic precession of the pulsar spin axis. The data are consistent with the general theory of relativity and provide some strong constraints on any alternative theory of gravitation.

Pulse arrival-time data

Most of the new information comes as the result of pulse arrival-time measurements, which now comprise approximately 1,000 observations spanning 4.1 yr. The data were obtained at frequencies near 430 and 1,410 MHz, using the 305-m radio telescope at Arecibo, Puerto Rico. The normal observing procedure involves adding together approximately 5,000 pulses, using a pre-computed ephemeris to define the expected pulsation period. The resulting mean pulse profile is then fitted by the method of least squares to a long-term average 'standard profile', to obtain the precise pulse arrival time. Because of improvements in equipment and techniques between 1974 and 1978, our timing accuracy has gradually improved[3-5] from ~1 ms to ~50 μs. Data have been acquired at intervals not exceeding 7 months, and in spite of the short period of the pulsar ($P = 0.059$ s), there has been no problem in keeping track of the number of elapsed pulse periods.

Our analysis of the timing data follows the formulation of Epstein[6], and proceeds by the following steps. First, the pulse arrival times are corrected from the location of the observatory to the barycentre of the Solar System, including a relativistic clock correction to account for annual changes in gravitational potential at the Earth. A correction is then made for the dispersive delay in the interstellar medium, using the frequency of observation as Doppler-shifted by the Earth's motion. Finally, the proper time t_p in the pulsar's reference frame is obtained by correcting for (1) the projection onto the line of sight of the pulsar's orbital position, (2) the integrated effects of gravitational redshift and transverse Doppler shift in the highly eccentric pulsar orbit, and (3) the gravitational propagation delay. These three corrections have magnitudes of order (v/c), $(v/c)^2$ and $(v/c)^3$ times the orbital period, respectively. On the basis of initial guesses for the various parameters that enter the timing equation (see Table 1), the pulsar phrase at the time of observation can be predicted from the relationship

$$\phi = \phi_0 + t_p/P - \dot{P}t_p^2/(2P^2) \qquad (1)$$

This phase should be very close to an integer; the difference, or phase residual in periods, is used in a least-squares solution for improved values of the model parameters.

Table 1 Parameters derived from timing data

Right ascension (1950.0)	$\alpha = 19$ h 13 min 12.474 s ± 0.004 s
Declination (1950.0)	$\delta = 16° 01' 08''.02 \pm 0''.06$
Period	$P = 0.059029995269 \pm 2$ s
Derivative of period	$\dot{P} = (8.64 \pm 0.02) \times 10^{-18}$ s s^{-1}
Projected semimajor axis	$a_1 \sin i = 2.3424 \pm 0.0007$ light s
Orbital eccentricity	$e = 0.617155 \pm 0.000007$
Binary orbit period	$P_b = 27906.98172 \pm 0.00005$ s
Longitude of periastron	$\omega_0 = 178.864 \pm 0.002°$
Time of periastron passage	$T_0 =$ JD 2442321.433206 ± 0.000001
Rate of advance of periastron	$\dot{\omega} = 4.226 \pm 0.002$ deg yr^{-1}
Transverse Doppler and gravitational redshift	$\gamma = 0.0047 \pm 0.0007$ s
Sine of inclination angle	$\sin i = 0.81 \pm 0.16$
Derivative of orbit period	$\dot{P}_b = (-3.2 \pm 0.6) \times 10^{-12}$ s s^{-1}

Quoted uncertainties are twice the formal standard errors from the least-squares fit.

As indicated in Table 1, our timing model contains 13 parameters of physical interest, all of which must be determined

---

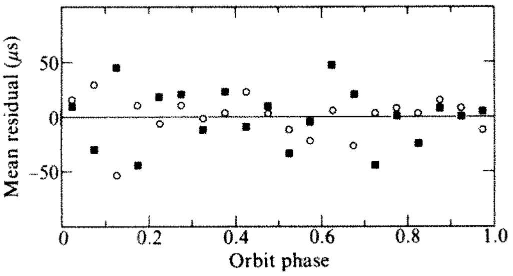

Fig. 1 Differences between observed and computed pulse arrival times for PSR1913+16, after averaging the data into 20 equal intervals of orbit phase for each of two observing frequencies: ■, 430 MHz; ○, 1,410 MHz. Parameter values listed in Table 1 were assumed for the computations, together with a dispersion measure of 171.64 cm^{-3} pc.

from the timing data. The parameters include the celestial coordinates of the system α and δ; the period and period derivative of the pular 'clock', P and $\dot{P}$; five Keplerian orbit parameters; and four parameters which measure effects of special and general relativistic origin. In addition to the advance of periastron, the relativistic terms include γ, which measures the variable part of the time delays contributed by transverse Doppler shift and gravitational redshift; sin i, the sine of the angle of inclination between the orbit and the plane of the sky, which is measurable because of its influence on both the gravitational propagation delay and the post-newtonian corrections to the elliptical orbit; and $\dot{P}_b$, the rate of change of orbital period. Further details concerning the timing model and methods of treating the data may be found elsewhere[3,6–8].

Parameter values based on data acquired through October 1978 are listed in Table 1. The weighted root mean square deviation of the 837 arrival-time measurements about the fitting function is 80 μs. In an attempt to search for possible low-level systematic departures of the data from the model, the residuals were averaged in 20 equally spaced segments of orbit phase. The resulting phase-averaged residuals are plotted in Fig. 1, with 430 MHz data and 1,410 MHz data shown separately. The points seem to be scattered at random about the zero line, with no phase dependent errors exceeding ~20 μs. We conclude that the timing model being used provides an exact fit to the data, within our measurement uncertainties, and therefore that no significant effects have been omitted from the analysis.

Except for $\dot{\omega}$, the relativistic parameters have not previously been measurable to useful accuracies. As shown in Table 1, all of them have now been determined to within ⩽20% accuracy. The most uncertain of the four quantities is sin i, because the terms in the timing equation on which it depends have the smallest amplitude[6,7], of order $P_b(v/c)^3 \approx 30$ μs. Because this amplitude is somewhat smaller than the typical individual measurement uncertainties, we performed an F-test for the significance of including sin i in the fit. The test gives a positive result at the 95% confidence level, and thus we believe that the value quoted for sin i is valid.

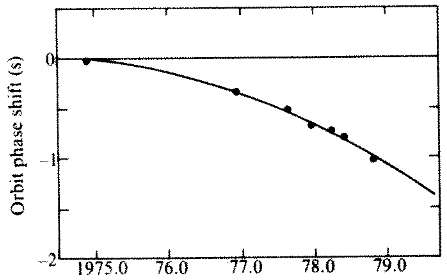

Fig. 2 Curves to delimit possible masses of the pulsar and its companion, based on the observed values of γ, sin i and $\dot{P}_b$. On these criteria, the most probable masses lie in the shaded region. The sloping straight line is the locus of all mass pairs for which the general relativistic contribution to $\dot{\omega}$ is the observed value, 4.266 deg yr^{-1}. The emphasised portion of this line is consistent with the measured values of γ and sin i and very close to the measured value of $\dot{P}_b$; it probably represents the best available estimates of the masses.

Together with the well determined Keplerian parameters, the values of γ, sin i and $\dot{P}_b$ provide strong constraints on the masses of the pulsar and its companion (m_p and m_c, respectively). These constraints can be illustrated conveniently in a diagram of pulsar mass against companion mass, as shown in Fig. 2. In constructing this figure we have used the relationships

$$\gamma = 0.002951\left(\frac{m_c}{M_\odot}\right)\left(\frac{m_p+2m_c}{M_\odot}\right)\left(\frac{m_p+m_c}{M_\odot}\right)^{-4/3} \text{ s} \qquad (2)$$

$$\sin i = 0.5083\left(\frac{m_c}{M_\odot}\right)^{-1}\left(\frac{m_p+m_c}{M_\odot}\right)^{2/3} \qquad (3)$$

$$\dot{P}_b = -1.70\times10^{-12}\,\frac{m_p m_c}{M_\odot^2}\left(\frac{m_p+m_c}{M_\odot}\right)^{-1/3} \text{ s s}^{-1} \qquad (4)$$

$$\dot{\omega}_{GR} = 2.11\left(\frac{m_p+m_c}{M_\odot}\right)^{2/3} \text{ deg yr}^{-1} \qquad (5)$$

which follow directly from equations summarised in ref. 3 and the parameters given in Table 1. Curves have been plotted in Fig. 2 bracketing the range of values of γ, sin i and $\dot{P}_b$ consistent with the data; they suggest a combination of pulsar mass and companion mass somewhere within the shaded region, that is $m_p \approx m_c \approx 1.6\,M_\odot$. According to equation (5), one would then expect to observe $\dot{\omega} = 4.58$ deg yr^{-1}. Because the observed value of $\dot{\omega}$ is well determined at ~10% less than this value, it seems that a much more probable solution for the masses lies somewhere along the emphasised portion of the sloping straight line, such that $m_p = 1.39 \pm 0.15\,M_\odot$, $m_c = 1.44 \pm 0.15\,M_\odot$, and that the observed rate of periastron advance is entirely caused by the general relativistic effect. In this case, the observed magnitude of $\dot{P}_b$ agrees with the value expected from gravitational radiation damping to within a factor 1.3±0.3. There is no compelling evidence for significant tidal or rotationally-induced contributions to $\dot{\omega}$.

Undoubtedly the most important new result of this work is the measurement of $\dot{P}_b$ with the sign and magnitude expected on the basis of gravitational radiation within general relativity. The validity of the measurement is clearly shown in Fig. 3, which shows the accumulating orbit phase error caused by assuming P_b fixed at its 1974.9 value, that is $\dot{P}_b = 0$. The measured points (which correspond to separate determinations of the time of periastron passage, T_0, for each of seven major observing sessions) are not well fit by a straight line. However, they fall very close to the plotted parabola, which represents the general relativistic prediction for $m_p = m_c = 1.41\,M_\odot$ according to equation (4). The data thus provide a striking confirmation of a longstanding prediction of the general theory of relativity, and an indirect proof of the existence of gravitational waves carrying energy away from the orbiting system.

Other possible contributions to $\dot{P}_b$ seem to be implausible, *ad hoc*, or of negligible magnitude. For example, differential galactic rotation and mass loss from the system contribute at most about ~1% (refs 9, 16, 21) of the observed value of $\dot{P}_b$. If the (as yet unidentified) companion object is a neutron star or a black hole, then tidal dissipation is also of no significance. Tidal effects could be important in a white dwarf companion, but the only white dwarfs consistent with $\dot{\omega} = 4.266$ deg yr^{-1} have either rapid rotation[9] or masses close to the Chandrasekhar limit. Such stars would produce either positive or negligible contributions[9,22,23] to $\dot{P}_b$. We conclude that the only straightforward interpretation of the observed orbital decay is in terms of gravitational radiation damping.

Gravitational radiation

It has already been pointed out[10,11] that most theories of gravity other than general relativity predict dipole gravitational radiation from an orbiting system like PSR1913+16. In these theories, the predicted dipole radiation is considerably larger than the quadrupole radiation in general relativity, and in some theories it even carries energy of the opposite sign[11]. Unless the two orbiting stars are within a few per cent of being identical in their ratios of gravitational binding energy to inertial mass (in which case the dipole radiation term vanishes) it is difficult to reconcile our measurement of $\dot{P}_b$ with any such theory. The data are also inconsistent with the suggestion that gravitational waves may be composed of half-retarded, half-advanced potentials, and would therefore carry no energy at all[12].

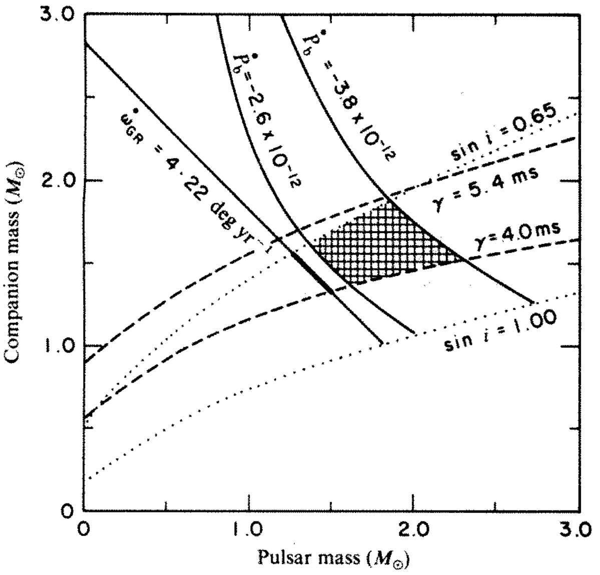

Fig. 3 The points represent measured orbital phase errors caused by assuming a fixed value of P_b. Uncertainties associated with each point are comparable with or smaller than the point itself. The plotted curve corresponds to the orbital period derivative predicted by general relativity if $m_p = m_c = 1.41\ M_\odot$.

An argument has been put forth[13,14] that a formula for energy loss due to gravitational radiation has not yet been derived consistently within general relativity, and that the quadrupole formula used[15,16] to derive equation (4) may be inaccurate because it ignores nonlinearities caused by radiation-reaction forces. As shown in Fig. 2, our data suggest that any such inaccuracy is not very large. The uncertainty associated with $\dot{P}_b$ will decrease rapidly with continued measurements over the next few years, so it will soon become evident if there is any significance to the small apparent discrepancy.

The new mass determinations are consistent with current ideas about neutron star structure and formation and with the hypothesis, based on evolutionary grounds, that the binary system consists of two neutron stars[9,17,18]. A main sequence helium star[19] can now be ruled out as a companion, because it would require $\dot{P}_b \approx -0.5 \times 10^{-12}$, about one-sixth of the observed value.

General relativity also predicts[15,20,24] that in this system geodetic spin–orbit coupling should cause the pulsar spin axis to precess at a rate $\Omega_p \approx \frac{7}{24}\dot{\omega}_{GR} \approx 1$ deg yr^{-1}. According to currently viable pulsar theories, a double-peaked pulse shape such as that observed for PSR1913+16 is probably caused by the rotation through our line of sight of a hollow cone of beamed emission. Thus, as the spin axis precesses, we should expect to observe different cuts through the radiation beam, probably accompanied by changes in pulse width and/or shape.

Such an effect has now been observed, as shown in Fig. 4. Here we plot the average pulse profiles observed in July 1977, June 1978 and October 1978, with the 1978 data smoothed so as to have the same time resolution (400 μs) as the earlier profile. The three profiles have been aligned at the leading edge and normalised so that the first component has identical height in all three cases. With this convention, the leading component does not seem to have changed significantly, but the central component has broadened substantially and moved towards the pulse centre. At the same time the separation between outermost peaks has progressively increased, and the third component has also broadened somewhat. The extreme trailing edge of the pulse seems to fall more rapidly in the October 1978 profile than in the earlier ones. However, this trailing edge is considerably wider than that observed[4] at 1,400 MHz, probably because of interstellar scattering. Consequently, this part of the pulse shape change may result from a change in the scattering time constant of the interstellar medium.

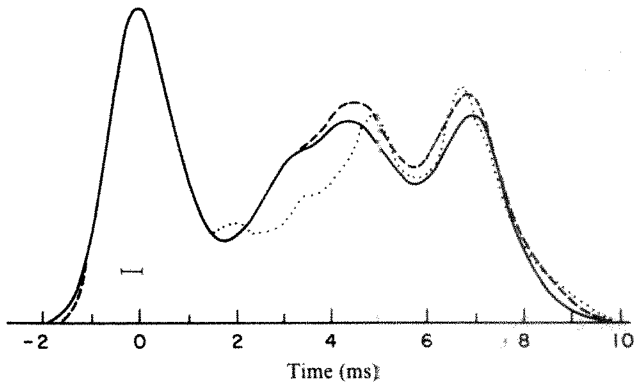

Fig. 4 Pulse profiles observed at 430 MHz in July 1977 (dotted line) and June (dashed line) and October (solid line) 1978. The central component has been gradually moving to the left and becoming broader, while the third component has shifted to the right. All profiles have been smoothed to the resolution indicated by the horizontal bar, 400 μs.

Changes of pulse shape towards a broader and more symmetrical profile suggest that precession is moving the observer's line of sight closer to the centre of the radiation cone. A geometry that accounts qualitatively for the observed changes is shown schematically in Fig. 5. More data will be required over a longer time interval, preferably including polarisation

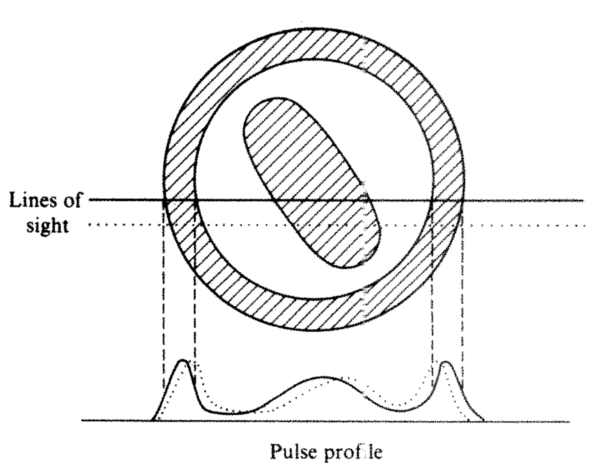

Fig. 5 A possible geometry to account for the pulse shape changes shown in Fig. 4. Shaded regions represent active portions of a hollow cone of pulsar emission; horizontal lines represent loci of the line of sight through the beam as the pulsar spins. Hypothetical pulse profiles are sketched below. As the spin axis precesses, moving a different portion of the beam into the line ofvt, the profile is expected to change. October 1978 (solid line); July 1977 (dotted line).

information, before any quantitative description of the observed changes of angle can be made.

Our measurement of the rate of change of orbital period is an entirely new test of general relativity, and at present the only one that depends on the theory's structure beyond the first post-newtonian approximation. The only straightforward interpretation of the data is that gravitational waves exist and carry energy away from an orbiting system at the rate predicted by general relativity. The conclusions that $m_p \approx m_c \approx 1.4\ M_\odot$ and $\dot{\omega} \approx \dot{\omega}_{GR}$ give strong support to the interpretation of the PSR1913+16 system as a pair of neutron stars, and provide an important test of the theory of late stages of stellar evolution. Finally, the observed precession of the pulsar spin axis provides a unique opportunity to obtain information on the shape of the pulsar radiation beam in two dimensions.

Vulcanian eruption mechanisms

Stephen Self
Department of Earth Sciences, Dartmouth College, Hanover, New Hampshire 03755

Lionel Wilson
Environmental Science Department, University of Lancaster, Lancaster, UK

Ian A. Nairn
New Zealand Geological Survey, PO Box 499, Rotorua, New Zealand

Application of a newly developed theory to volcanological observations of explosive eruptions shows that previous estimates of pre-explosion gas pressures may be over-estimated by an order of magnitude.

THE andesite stratovolcano Ngauruhoe, in North Island New Zealand, erupted explosively during the afternoon of 19 February 1975. The eruption was closely observed and filmed[1]. There were two main phases. A 1.5-h gas-streaming phase[2] produced an 11–13 km high eruption column. This phase was followed by a series of discrete cannon-like explosions at 15 to 50 min intervals over a period of 5 h (ref. 2). The latter type of activity is common on many andesite and basaltic andesite volcanoes, for example Asama[3] and Arenal[4], and is referred to as vulcanian type activity[5,6].

Vulcanian explosions have been studied from several recent eruptions[7,8] and display common characteristics: the rock mass ejected per explosion is usually 10^2 to 10^6 tonnes (refs 3, 6) and often contains a high proportion ($\geqslant$50%) of nonjuvenile material; during active periods, intervals between explosions vary from <1 min (Anak Krakatoa[6]) to about 1 day (Asama[3], Sakurazima[9]); pyroclastic avalanches (*nuées ardentes*) are often produced[8,10,11].

Nairn and Self[2] recently described the February 1975 eruption of Ngauruhoe and interpreted the generation of cannon-like explosions in the light of concepts established in the volcanological literature. Here we use newly developed theory to re-analyse the largest of the cannon-like explosions (at 18.10 h on 19 February) and discuss an alternative model of vulcanian explosions. The model is constrained by paucity of data, particularly on lava tensile strengths and weight percentages of fine ejecta and released gases, but does point out the type of data required for improved analysis of vulcanian eruptions. McBirney[12] recently reviewed controls on explosive andesitic eruptions and criticised the use of the Bernouilli equation to derive pre-explosion pressures. However, use of the 'gun-barrel' equation, recommended by McBirney, is also open to criticism. This article revises some earlier computations[2] of pre-explosion pressures at Ngauruhoe and demonstrates that gas pressures required to generate vulcanian explosions are probably lower than previously thought.

Direct observations of discrete vulcanian explosions

The best documented discrete explosion at 18.10 h consisted of the expulsion of a cloud of gas containing fragments with a wide range of sizes. The initial velocity was supersonic, resulting in a shock wave[2]. The position and extent of the cloud was recorded on a series of photographs timed with sufficient accuracy for estimates to be made of the average velocity between each pair of photographs. Figure 1 shows the resulting variation of velocity with height; an estimate of errors has been included.

0028-0836/79/0277—0440$01.00

It is known that the velocity of a cloud of material ejected into the atmosphere at high speed must decrease approximately exponentially with height[13] after passing through a maximum value, thus one estimate of the initial velocity can be obtained by fitting a straight line to the data shown in Fig. 1: the value indicated is ~400 m s^{-1}. A second estimate comes from consideration of the dynamics of the shock wave propagation: to produce the apparent shock velocity of at least 600 m s^{-1} the velocity of the ejected slug of debris would have to be not less than 340 m s^{-1} (ref. 2) calculated for a one-dimensional case. The true maximum velocity of the ejecta probably lies between these values.

Theory of vulcanian explosions

Discrete, intermittent explosions, with the exception of phreatomagmatic explosions, must be the result of the sudden release of pressure in a gas by the failure of some form of retaining medium. In the vulcanian case the gas may be magmatic or meteoric. It seems improbable that a layer of unconsolidated clasts at the top of the conduit can substantially retain the build-up of an appreciable gas pressure. We assume, therefore, that magma is always involved in such events. New magma rises in a conduit after a previous explosion and cools at its upper surface, forming a 'cap'.

The compressional strength of dolerite is known to remain nearly constant[14] with temperature up to 950 °C; in view of the lack of evidence to the contrary, we assume that tensile strengths of rocks, commonly quoted to be of the order of 10% of compressional strengths, also remain constant up to this temperature. Tensile strengths (at low pressures) of 100–200 bar are deduced for rocks of andesitic type from the limited data available[14,15]. To obtain an estimate of the thickness of crust sufficiently cool to provide a strength of this order, standard treatments on heat flow can be used[16]. Cooling from magmatic temperature (say 1,000 °C) during the 50 min interval before the 18.10 h explosion could have produced a layer, cooler than 950 °C, which was up to 15 cm thick, the distance a thermal wave can travel in rock in this time. Clearly, cool fragments of rock debris smaller than 30 cm in diameter would be efficient heat sinks on this time scale. Indeed, the addition of 10% by weight of such debris, derived from the conduit walls or the fall-back in the vent area from earlier explosions, would cool a layer of any desired thickness to 950 °C.

The pressure in a mixture of degassing magma and heated groundwater prior to an explosion would be equal to the tensile strength at depth H below the cap by an amount $\sigma_r gH$ where σ_r is the magma density and g the acceleration due to gravity. At a depth of 500 m in partially degassed magma of bulk density 1,000 kg m^{-3} the added pressure would be about 50 bar.

Many attempts have been made to relate the ejection velocity of fragments from volcanic explosions, particularly those of vulcanian type, to the initial pressure of compressed gas driving the explosion[6,8,12,17,18]. All of these treatments are essentially based on a modified form of the Bernouilli equation. We are no longer satisfied that this equation adequately represents the conditions in any actual volcanic explosion.

The simplest treatment of an explosion driven by expanding gas is one in which it is assumed that complete decompression to atmospheric pressure occurs, and that all of the internal energy released by the expansion is used to accelerate the explosion products, both released gas and clasts, to the same velocity. The energy equation[19] is then:

$$-\int \frac{\mathrm{d}P}{\rho} = \int g\,\mathrm{d}h + \int u\,\mathrm{d}u \qquad (1)$$

in which ρ is the bulk density of the eruption products, P is the pressure, g is the acceleration due to gravity, h is the vertical coordinate and u the velocity. ρ must be defined in terms of n, the weight fraction of released gas in the exploding mixture, σ, the gas density, and σ_r, the clast density:

$$\frac{1}{\rho} = \frac{n}{\sigma} + \frac{1-n}{\sigma_r} \qquad (2)$$

σ is in turn dictated by the temperature, pressure and composition of the gas; in the present circumstances it is adequate to assume that the perfect gas law applies. It is necessary, before integrating equation (1), to decide whether the gas expansion will be more nearly isothermal or adiabatic; the deciding factor is the efficiency with which heat can be transferred from clasts to gas and depends on the clast size distribution[20]. In the case of strombolian explosions, in which the time scale is very short, an adiabatic approximation is valid[13]. For vulcanian explosions, the best solution probably lies between the isothermal and adiabatic cases. The results of integrating (1) using (2) and an initial temperature T_i are:

$$nRT_i \ln (P_i/P_f) + \frac{(1-n)}{\sigma_r}(P_i - P_f) = g\Delta h + \tfrac{1}{2}u_f^2 \qquad (3)$$

in the isothermal case and, in the adiabatic case:

$$nRT_i \frac{\gamma}{(\gamma-1)}\left[1-\left(\frac{P_f}{P_i}\right)^{(\gamma-1)/1}\right] + \frac{(1-n)}{\sigma_r}(P_i - P_f) = g\Delta h + \tfrac{1}{2}u_f^2 \qquad (4)$$

where P_i is the initial pressure driving the explosion, P_f is the final pressure, assumed equal to atmospheric, Δh is the vertical distance over which the gas decompression occurs, γ is the ratio of the specific heats of the gas, R is the gas constant and u_f is the final velocity. If numerical values are inserted, it is generally found that the term $g\Delta h$ can be neglected for explosions in which the expansion of gas occurs over a vertical distance of less than a few hundred metres.

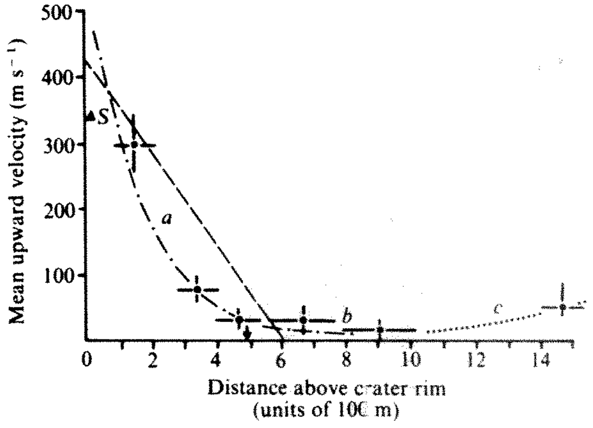

Fig. 1 Deceleration of 18.10 h plume from analysis of still photographs. Errors shown as bars. Straight line fitted between maximum and minimum values; curved line approximates exponential deceleration. S is speed of sound in air for reference. The steep portion of curve (a) represents deceleration in gas thrust phase[7]; the flat portion (b) represents slow, stable velocity condition while mixing with air and column collapse takes place; (c) is a slight increase in velocity at beginning of convective thrust phase. The downwards pointing arrow indicates onset of column collapse.

The modified version of the Bernouilli equation is usually written:

$$P_i - P_f = \tfrac{1}{2}\sigma_r u_f^2 \qquad (5)$$

in terms of the variables already defined. There has been some discussion[12] as to what density should appear in this equation: σ_r (as written here) or ρ. Comparison of equations (5) and (3) reveals the essential problem with the modified Bernouilli equation: it only approximates the correct expression if n is sufficiently small (and if Δh is also small). The values of n encountered in real volcanic explosions (say 0.1 to 30 weight per cent if plinian, vulcanian and strombolian events are included) are always too large for this approximation to be true.

We have argued above that the build-up of pressure beneath a restraining cap may be the source of vulcanian explosions. In such a case the mixing of gas and clasts from the disrupted cap and the surrounding rocks may not be great in the early part of the motion; a physical model based on the motion of a solid block of coherent (or shattered) rock overlying a gas body of similar cross sectional area may be more applicable. If the vertical extent of the cap is L and its density is σ_r, and if the gas body beneath the cap has vertical extent X, initial temperature T_i, pressure P_i and gas constant R, then simple geometry shows that

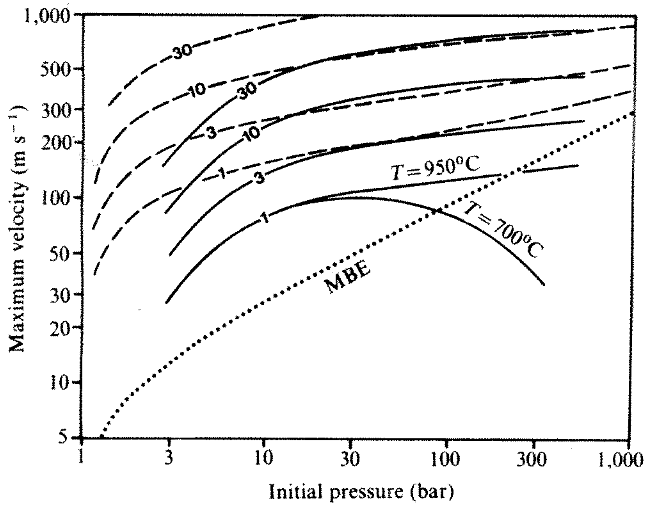

Fig. 2 Maximum velocity of explosion products as a function of initial pressure driving the gas expansion for various types of volcanic explosions. The dotted line MBE is the modified Bernouilli equation (equation (5)). The dashed lines are calculations using equation (3) and are labelled by the wt % gas (taken to be steam) used in the calculations. For these curves perfect thermal contact between gas and clasts is assumed. The solid curves, also labelled by wt % gas in the exploding mixture, represent solutions to equation (7); the gas cools adiabatically during its expansion from an initial temperature of 1,220 K; in the case of the curve for 1% gas, the effect of reducing the initial temperature by 250 degrees is shown. The dashed and continuous curve for each gas content bracket the upper and lower limits of velocity for a given driving pressure in vulcanian explosions. When the ejecta are predominantly less than 10 mm in diameter, velocity values correspond more closely to the dashed curves.

$$\frac{X}{L}=\left(\frac{n}{1-n}\right)\left(\frac{\sigma_r R T_i}{P_i}\right) \tag{6}$$

so that the solutions may again be expressed in terms of n, the gas weight fraction in the explosion products. The equation of motion for the cap in the vertical h direction is

$$P-P_f=L\sigma_r\ddot{h}+L\sigma_r g+\tfrac{1}{2}\rho_a C_D\dot{h}^2 \tag{7}$$

where P is the general value of the pressure during the expansion. P is given by

$$P=P_i\left(\frac{X}{X+h}\right)^{\gamma} \tag{8}$$

initially, since the expansion is adiabatic until some small clasts begin to mix with, and supply heat to, the gas. The final term in equation (7) represents atmospheric drag acting on the rising cap: C_D is a drag coefficient with value close to unity and ρ_a is the atmospheric density. Equation (7) is readily integrated numerically using equations (6) and (8) to yield the maximum velocity, u_f, of the products during the explosion process. The results of such calculations, and also of the use of the simpler equations (3) and (4), are summarised in Fig. 2, in which u_f is shown as a function of P_i for a range of values of n in each case.

It is likely that at least 50 wt % of the fragments ejected during the 18.10 h explosion were smaller than 3 mm (ref. 2) and able, therefore, to maintain thermal equilibrium with the gas during the period (of the order of 0.5–2 s) of acceleration of the largest clasts, implies that the velocities corresponding to equation (3) (isothermal case) may be more appropriate for vulcanian explosions than those derived from equation (4); the solutions to equation (7) certainly represent the lowest possible velocity that corresponds to any particular pair of values of n and P, as they give the greatest weight to energy losses. The speeds given by equation (4) are very close to those from equation (3) at low pressures and fall to about 70% of the equation (3) speeds as the pressure approaches 1,000 bar. The n and P values given below are means of equations (3) and (7) biased towards equation (3) on the basis of this argument.

The following combinations of initial gas pressure and released gas wt % are implied by the observed maximum velocity of 400 m s^{-1}: for $n=30\%$, $P_i=2$–5 bar; for $n=10\%$, $P_i=10$–30 bar; for $n=5\%$, $P_i=40$–100 bar; for $n=3\%$, $P_i=100$–300 bar. We argued above that the likely range of values of tensile strength of andesite at sub-solidus temperatures is 100–200 bar (refs 14, 15). Then the above permutations of pressure and gas content would imply that the explosion products of the 18.10 h event contained 2–5 wt % water. It was estimated[2] that equal proportions of juvenile and nonjuvenile material were expelled in the explosion, and so if it is assumed that all of the water were juvenile, 4 to 10 wt % would be required in the magma. The lower end of this range is comparable to the measured primary water contents[21,22,28] of andesite magmas, but it is probably implied that some groundwater water was also involved.

Magma volume and conduit shape considerations

The total volume of rock expelled in the 18.10 h explosion and four other similar outbursts on the same day was about 5×10^5 m^3 dense rock, approximately half of which was juvenile. We may assume that juvenile material was re-emplaced in the upper parts of the volcano between explosions, so that a total of about 2.5×10^5 m^3 of pre-existing cone material was excavated.

This volume cannot have been removed from a localised region near the vent because we know[2] that there was little significant change in the geometry of this region during the explosive activity: if 2.5×10^5 m^3 is taken to occupy a vertical cylinder with length equal to diameter, the required dimension is 68 m, which is greater than the crater bottom diameter. There is an added reason why such a geometry is unlikely. Heating of groundwater near the magma body is only possible if heat can penetrate the required distance in the time available; the repose period before the 18.10 h explosion was 50 min, and thermal waves can only travel distances of the order of a few tens of centimetres in rock in this time[16].

A long, cylindrical conduit feeding the vent is the geometry which maximises the chances of groundwater being involved in the explosions. Ngauruhoe stands ~950 m above the surrounding topography; if a vertical length of, say, 500 m were involved, the excavated cylinder needed to provide both the juvenile and nonjuvenile debris for all five major explosions would have had a diameter of 32 m. Figure 3 shows the situation envisaged: a long, cylindrical conduit about 20 m in diameter containing vesicular magma of mean density ~1,500 kg m^{-3}, cooled at the surface and chilled at its contact with the cone material, contains

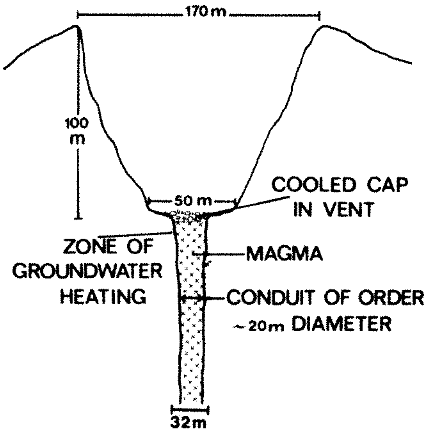

Fig. 3 Schematic of proposed cross-section through crater region of Ngauruhoe before the 18.10 h explosion.

clasts which have fallen into the conduit from earlier activity. Water in these clasts and in the cone material immediately surrounding the magma is heated to near-magmatic temperatures and, together with exsolved juvenile magmatic water, drives the explosion when the cap over the vent fails. It is not possible to estimate accurately the relative contributions from magmatic water and groundwater. The 18.10 h explosion must have removed a rock layer some 5 m thick from the conduit walls to satisfy the observed mass. Only a small fraction of this rock and its pore water could have been heated by conduction in the 50 min before the explosion, although water and steam in interconnected fissures may have been heated by convection. However, in the one to two seconds after the failure of the magma cap, that is during the period of acceleration of large blocks, rapid turbulent mixing of small fragments of disrupted magma and released groundwater would have taken place. It was shown above that up to 50% of the mass of disrupted magma could interact thermally with the evaporating water on this time scale. If all the available water in the wall rock layer were involved in the explosion, a water content of 2–3% in this rock would be consistent with the expected water contribution from the magma, as noted above.

In the above treatment we have not found it necessary to invoke the rapid mixing of juvenile material with groundwater that might lead to flash boiling[23]. This mechanism has been proposed as a means of creating pressures of the order of 3–5 kbar, similar to the pressures deduced for high velocity explosions[17] by applying the Bernouilli equation. Our analysis does not require such high pressures to initiate the explosion process.

Eruption column behaviour

The rise height, h, of the convective plume from the 18.10 h explosion can be computed from a formula for convective rise from an instantaneous source and compared with the observed height: h, in metres, is given[24] by

$$h = 1.87 Q^{1/4} \tag{9}$$

where Q is the released heat energy in joules. The 18.10 h event emitted[2] 2×10^8 kg of rock, of which about half was juvenile (that is, hot and able to contribute to driving convection). However, about half of the material injected into the plume was lost almost immediately (after 12–15 s) by the partial collapse of the column to form pyroclastic avalanches[2]. Thus, the heat available to drive convection is estimated to have been a maximum of 4×10^{13} J, leading to a predicted column height, h, of 4,700 m. The observed value[2] was at least 4,000 m above the vent, the discrepancy implying an efficiency of heat utilisation of about 50%.

This may be compared to values much closer to 100% found for maintained plumes produced by other eruptions[25] and also to the value found for a maintained plume at Ngauruhoe. During part of the gas-streaming eruptive phase, lasting from 13.25 to 13.45 h, prior to the series of discrete explosions, a 10 km high (above crater) convecting column existed[2] over Ngauruhoe. The equivalent of equation (9) for continuous column convection is[24,25]

$$h = 8.2 \dot{Q}^{1/4} \tag{10}$$

where h is the column height in metres as before and $\dot{Q}$ is the rate of release of heat energy in Watts. A 10 km column height implies a mass eruption rate of 3.2×10^6 kg s^{-1} (ref. 25). The estimated volume[2] erupted in this cloud was 1.6×10^6 m^3 dense rock which, averaged over 20 min and using the density of andesite equal to 2,550 kg m^{-3}, corresponds to 3.4×10^6 kg s^{-1}, in good agreement with the above value, suggesting that the efficiency of conversion of heat to work was close to 80% in this case.

Vulcanian explosions are very common at the many active andesitic strato-volcanoes clustered along subducting plate margins. Some of these eruptions are more violent than those described from Ngauruhoe[8,26]. However, previous estimates of pre-explosion over-pressures have generally been too large, and this article demonstrates that relatively small pressures are probably adequate to produce the observed behaviour during this type of eruption. Basaltic andesite magmas have water contents comparable to those deduced for the explosions[21,22,28], and the involvement of groundwater is possibly a significant feature of the events, but not an essential feature as proposed by Schminke[27]. It is not necessary to invoke violent mixing of juvenile material and groundwater on a large scale to explain the explosions though such mixing on a small scale may be a significant feature of some vulcanian explosions. Eruption cloud heights can be related to the rate of release of juvenile material during steady gas-streaming activity, and to the amount of released material in discrete explosions, using the formulae found to apply to larger-scale eruptions[25].

Concentrations of metals in very small volumes of soil solution

Todd Hinkley
US Geological Survey, Denver, Colorado 80225

A new method of sampling very small amounts of soil solution (0.3 g) shows that soil solutions contain high concentrations and unusual proportions of metals. In the soils studied, the solution is close in both metal proportions and total metal mass to what may be taken up annually by the growth of plants at the sites sampled. Composition of soil solution varies seasonally and with depth in soil.

A FUNDAMENTAL problem in soil science and plant nutrition has been the determination of the true chemical composition of the films of solution which surround particles of normal, unsaturated soils and which are in contact with the roots of growing plants. Attempts to determine metal concentrations in soil solution have been hampered because conventional analysis requires large amounts of solution, and the collection of large samples generally alters the composition of the solution[1].

A method for sampling very small amounts of solution from undisturbed, unsaturated soils in the field was used for this study, and techniques originally used in nuclear geochemistry have been used to analyse the samples. This has the advantage that much smaller samples (roughly single-drop size) may be analysed to greater accuracy for both major metals and related trace metals than has previously been possible.

Field selection and sampling method

The soil solution is rapidly blotted onto a stack of specially cleaned absorbent paper. In the field, the sampler cleared a flat space at an appropriate horizon in the soil, and placed a porous-plastic (Nuclepore) filter on the soil surface. Then, wearing an acid-cleaned polyethylene glove, the sampler pressed with his thumb a stack of six specially cleaned and weighed 4-cm filter paper disks tightly against the plastic filter for a few seconds. The stack was put into a clean Teflon bottle and tightly sealed for reweighing in the laboratory. Rare contamination of the solution samples with particles from the soil was revealed by easily visible brown staining of the white absorbent paper, and proved in all cases to be associated with rupture of the plastic filter. The few such samples were discarded.

Two published reports[2,3] have proposed this sampling method in principle, and results have been reported by Schuffelen *et al.*[4] of a study using a similar sample collection method.

The study site, Thompson Canyon, comprised an area of 12.2 km^2 in the northern part of Yosemite National Park in the central crest region of the Sierra Nevada of California at an altitude of ~2,900 m (meadow surface). The area was selected because of freedom from disturbance by human activity, uniformity of rock (quartz monzonite) which has provided material to the soil since glaciation 10,000 yr ago, the fact that all water entering the watershed comes from precipitation, and the rather simple and stable assemblage of plant and animal species. The watershed has been used since 1970 for studies of geological and biological fractionation of metal families in terrestrial food chains[5-9].

Methods of analysis and soil sampling

Metals determined in the samples were the alkali metals K, Rb and Cs and the alkaline earth metals Ca, Sr and Ba. These metals were selected because the members of each family exhibit a narrow but definite range of behaviour in nature owing to similar electronic properties and varying ionic size. The metals have widely varying geochemical abundances, and most have been used extensively in soil science investigations. Na and Mg were not suited to the same analytical techniques as the six metals reported in this study.

Stable isotope dilution mass spectrometric analysis was used for all determinations. It is the most sensitive and accurate method known for determining very small amounts of many metals; the extremely small samples (~0.3 g solution) collected in this study were readily analysed for the six metals using this technique. The most extensive development and application of the technique has been in the field of nuclear geochemistry, and its use in this study is possible largely through its refinement for analysis of lunar material[10]. A known amount of isotopically enriched tracer was equilibrated with the sample so that the resultant isotopic ratio was a mass-weighted average of the isotopic composition of the enriched tracer and the natural isotopic composition of the sample. This resultant ratio was measured on a solid-source, thermal-emission mass spectrometer, and the sample mass calculated.

Seventeen samples of soil solution were analysed. These were taken from three localities (total of five horizons). Soils selected (entisols) were (1) a humus-rich soil in the centre of the broad, deep meadow in the bottom of the glacial valley, sampled in a single near-surface zone containing sedge roots; (2) a soil (humus-rich near the surface but less deeply developed than the meadow soil) perched on a narrow hillslope terrace, from which solution was sampled at both 5-cm (growth zone of shallow-rooted herb and sedge plants) and 30-cm depths (zone of deeper rooted plants such as large lupine); (3) a soil on the boundary of

conifer forest and meadow, supporting both conifers and meadow plants.

For sample preparation the filter disks were leached of sample using 20 ml of 0.1 M, highest purity HCl for several hours at 55 °C in an acid-cleaned quartz centrifuge tube and then centrifuged to precipitate fibres. Aliquots of this solution were removed with a pipette, isotopically spiked, and analysed for metals.

Tracers for all six metals were mixed together and added to aliquots of solutions made up from soil solution samples. The six metals were analysed in the mass spectrometer without chemical separation. Actual metal masses that were determined ranged from 160×10^{-9} g for K to 0.02×10^{-9} g for Cs, with blanks always less than 10% of these masses. To minimise contamination, special precautions were taken; these involved clean rooms, ultra-pure reagents, ultra-clean apparatus, and low contamination procedures in the field[11].

The accuracy and precision of the soil solution sampling and analytical method were tested using a homogeneous stock solution containing metals in concentrations very similar to those of the soil solution. The stock solution was sampled in two different ways. In one, an aliquot was taken directly from the bottle, spiked, and analysed with minimum treatment. In the second, a sample was blotted onto cleaned filter paper through a Nuclepore plastic filter and removed by leaching, a method analogous to the method of sampling the soil solution in the field. The data (not presented here) show that passage of moisture through the plastic filter and subsequent acid extraction from the absorbent paper do not introduce any large errors: results obtained using the two ways of sampling the known stock solution agreed within a few per cent.

In addition, reproducibility of results from actual field samples was tested by two methods. (1) Two samples of soil solution were taken in rapid succession directly from the cleared soil surface in the field, only a few centimetres apart (results plotted as double data points in Fig. 1, 14 June collection, perched hillslope soil; Cs and Ba analyses failed on one of the samples). At the same site, a soil sample (1,500 g) was thoroughly stirred in a clean polyethylene pan and two solution samples were collected from it in rapid succession (plotted as double points in Fig. 1, 22 July collection). As shown in Fig. 1 the variations in the duplicates are important fractions of the total masses, especially for Ca, but generally both values in each duplicate pair are close, even for Ca, and both fit well within the seasonal trend plotted. The variation must be attributed to inhomogeneities in the soil on a scale of a very few centimetres.

In a primitive version of the method used in this study[12] the bottom disk of the stack of absorbent papers was in direct contact with the soil and was discarded. This method introduced errors because the heavier alkaline earth metal ions (Sr and Ba) were preferentially retained in the bottom disks of the stack, through which the sample first passed. This finding led to the use of the porous plastic filter between soil and absorber during collection.

To clean the absorbent paper the Whatman No. 40 ashless, cellulose-acetate filter paper disks (5.5 cm) were batch-cleaned by leaching for 24 h in each of three successive 55 °C baths of 25% HCl solutions of increasing purity (analytical reagent grade, G. Frederick Smith distilled, National Bureau of Standards distilled). Moderately thorough water rinses (to *p*H 4 or 5) were used between each acid bath; highest purity rinse water was sucked through a few disks at a time on a Buchner funnel. The disks were vacuum dried between each acid bath. The series of HCl leachings was followed by a similar series in 0.5% highest purity HF and in 1% NH_4Cl at *p*H 7. The final rinse, after the NH_4Cl, was very sparing, so that some NH_4^+ would be left on the paper (E. E. Dickey, personal communication). The 0.4 μm pore size Nuclepore filters were cleaned in the same way as the papers. The HF and NH_4Cl steps reduce by 10-fold a troublesome Ba analytical blank, compared to that for a simple HCl sequence[12].

Results and discussion

Compositions of soil solution are quite different from those of any phreatic and stream waters in the watershed and elsewhere[13–15]. Metal concentrations in soil solution samples taken near the soil surface were as much as 1,000 times higher than those in phreatic water or stream samples collected at the same location (Table 1). Soil solution is the only type of water in the

watershed that has higher concentrations of alkali metals than alkaline earth metals. Stream water, phreatic water, and snow all contain more alkaline earths than alkalies. In no other natural waters measured are the concentrations of Rb and Cs, either absolutely or relative to K or to the alkaline earth metals, as large as they are in soil solution.

Solutions were collected at various times in the summer, at various soil depths, and from various soil types. The data are plotted in Fig. 1. In solutions near the surface (5 cm depth) of humus-rich soils, the concentrations of alkali metals (K, Rb, Cs) are highest in the autumn (mid-meadow and perched hillslope soils). In samples taken at greater depth below surface (30 cm, more mineralic zones), the alkali concentrations are lowest in the autumn (perched soil). For these deeper zones the seasonal trend appears less distinct in Fig. 1 only because the absolute concentrations and their changes are smaller, and because the scale of the plot has not been expanded.

Three possible factors influencing the seasonal soil-solution composition are the following: (1) metal uptake and release of metals by the standing crop of plants; (2) through-flow of solutions having different metal contents, and (3) uptake and release of metals by humus and clay in soils, in response to temperature, *p*H, or other physical and chemical factors. As for the effects due to the growth of plants, the mass of metals in soil solutions above the water table in mid-meadow is comparable to the mass of metals in the leaves of the standing crop of sedge (Table 4). Metal ratios in sedge leaves vary strongly with time of season[16], but these variations may represent only internal redistribution of metals between the leaves and the root systems of these plants. Variation in soil-solution composition caused by through-flow of soil solutions of variable composition is unlikely in these poorly drained soils, except in the earliest snow-melt part of the season. *p*H and temperature may affect the release of metals from humus and clay; *p*H was between 4 and 5 at all times of the season for all soils and average soil temperatures can rise measurably in mid-season. Equilibration times needed to replace metals in soil solution from the humus and clay reservoirs have not been determined for the soils of this study.

Table 4 Comparison of masses of metals in soil solution and in annual plant productivity

Metal	In soil solution	In annual plant productivity
K	7,000	14,000
Rb	71	81
Cs	11	8.5
Ca	11,750	5,200
Sr	32	96
Ba	64	81

Mid-meadow soil; mass of metals in solution to 10 cm depth; plant values from standing crops of sedge leaves; from unpublished data of Patterson and Elias; data in g per hectare.

Apart from seasonal variations, the major differences between the soil solutions collected near the soil surface (humus-rich zones) and those collected at greater depths (mineralic zones) are the following: (1) the metal concentrations are generally higher in the near-surface samples, and (2) alkali metals are more abundant relative to the alkaline earth metals in the near-surface samples. K/Ca ratios are most commonly greater than unity in the deeper zones. It is empirically true in samples from the field area of this study that, in direct correspondence to the composition of the shallow and deep soil solution, the leaves of shallow-rooted plants (sedges) have higher K/Ca ratios than those of more deeply rooted plants (conifers)[16]. Roots of these plants were present in the respective zones at the actual sampling sites.

The moisture contents of the soils sampled in this study (Table 2) are high and do not vary greatly. There are distinct differences between shallow, organic-rich soils and deeper, mineralic soils, but these subalpine soils do not dry out through the summer as do soils in other environments. The effect of lowered moisture content on the absolute or relative concentrations of the two families of metals determined are not known from the experiments of this study; it is accepted that changes in moisture content alter the distribution of monovalent and divalent metals between soil and solution[17], but it seems that the seasonal variation in solution metal composition observed in this study (Fig. 1) is to be associated with other factors. It is not known whether samples large enough for analysis could be collected by the blotting technique from soils much less moist than those of this field area.

The data presented in Table 3 show that in the particular non-agricultural soils of the study area the reservoir of metals contained in soil solution is much smaller than the reservoir available as exchangeable cations. In the study area the mass of metals in the soil solution is approximately equivalent to the mass turned over by plants in the annual growth cycle (Table 4). The proportions of the metals in the solution reservoir are very different from those in the exchangeable cation reservoir: in soil solution, the alkali metals seem to be relatively more abundant than the alkaline earth metals, whereas in the exchangeable cation reservoir the reverse is true (Table 3, K/Ca values 2.1 and 0.12, respectively).

This work was done in collaboration with C. Patterson (Division of Geological and Planetary Sciences, California Institute of Technology) and was supported by NSF grant GB 31038 and grants from the Geological Society of America.

Crystal structures of *Streptomyces* subtilisin inhibitor and its complex with subtilisin BPN′

Y. Mitsui, Y. Satow*, Y. Watanabe, S. Hirono & Y. Iitaka

Faculty of Pharmaceutical Sciences, University of Tokyo, Hongo, Tokyo 113, Japan

Crystal structure of a microbial protein proteinase inhibitor SSI (Streptomyces *subtilisin inhibitor) and its complex with subtilisin BPN′ were solved at 2.6 Å and 4.3 Å resolution respectively. The mode of binding to the proteinase of SSI is compared with that of bovine pancreatic trypsin inhibitor, soybean trypsin inhibitor and the substrates. Stereochemical considerations for the possible evolutionary relationship between SSI and pancreatic secretory trypsin inhibitor are presented.*

MANY protein proteinase inhibitors from animal and plant tissues have been extensively studied[1]. However, bovine basic pancreatic trypsin inhibitor[2–4] (Kunitz, BPTI) and soybean trypsin inhibitor[5,6] (Kunitz, STI) are the only protein proteinase inhibitors which have been studied by X-ray diffraction. *Streptomyces* subtilisin inhibitor (SSI), isolated from *Streptomyces albogriseolus* by Murao and Sato[7,8], is one of the few well characterised microbial protein proteinase inhibitors. SSI has been characterised chemically and spectroscopically and by the X-ray diffraction studies carried out in a collaborative study involving nine laboratories, led by K. Hiromi (summarised in ref. 9). Unlike classical trypsin inhibitors[1], SSI strongly ($K_{\rm I} \simeq 10^{-10}$ M)[10] and specifically[8] inhibits bacterial alkaline proteinases (such as subtilisin BPN′), although it also weakly inhibits α-chymotrypsin and trypsin ($K_{\rm I} \simeq 10^{-6}$ and 10^{-4} M, respectively)[11,12]. SSI is a stable dimer[13] (I_2) composed of two identical subunits each of molecular weight 11,483 (ref. 14). In the trigonal crystals ($P3_121$, $a = b = 40.6$ Å, $c = 115.2$ Å) of SSI analysed here, the two subunits are related by a crystallographic diad[15].

The inhibition of subtilisin BPN′ by SSI occurs when one subunit (I) of SSI inhibits one molecule (E) of subtilisin[16,17], and the molecular species of the SSI · subtilisin complex in solution was characterised as E_2I_2 (ref. 18). The orthorhombic crystal of this complex ($I222$, $a = 77.5$, $b = 186.9$, $c = 69.6$ Å), analysed here, contains half the complex molecule (EI, MW ~ 39,300) in an asymmetrical unit[15]. Furthermore, the amino acid sequence of the subunit of SSI, a single polypeptide chain with two disulphide bridges, was determined by Ikenaka *et al.*[14]. Chemical evidence, including the unusual susceptibility of the Met-73–Val-74 bond to trypsin and α-chymotrypsin, led these workers to propose that this was the susceptible bond[14]. We have shown here that this hypothesis is correct by crystal structure analysis of the complex molecule.

Structure of SSI

The structure analysis of SSI at 4 Å resolution was reported previously[19]. For 2.3-Å resolution study, about 13,000 reflections (including Friedel pairs) were collected for each of the three heavy-atom derivatives, $(NH_4)_2Hg(SCN)_4$, $(NH_4)_2Pt(NO_2)_4$ and ethylmercuric thiosalicylate, for which the root-mean-square (r.m.s.) heavy-atom structure factor/r.m.s. lack-of-closure error was 38.6/19.3; 34.9/18.6; and 36.8/19.6 electrons, respectively. Detailed analysis of the statistics, however, revealed that the phasing between the 2.3-Å and 2.6-Å spheres was unreliable so that the maximum resolution of the map was 2.6 Å. The map was interpreted using a half-mirror device[20] and the 1 Å = 2 cm Kendrew model. For rapid measurement of the coordinates of the wire model, a semi-automatic device using two He–Ne laser tubes and magnetic encoders was developed[21]. Details of the structure analysis will be published elsewhere[22].

A schematic drawing of the subunit has been previously presented[23]; the electron densities are easily interpretable except for the N-terminal four residues almost missing) and the region Ala-62–Met-70, where only the approximate course of the main chain can be traced. The size of the subunit is about 25 × 35 × 40 Å, whereas that of the dimer shown in Fig. 1 is about 30 × 40 × 65 Å. The subunit has a five-fold antiparallel β-sheet twisted as usual[24], and two short α-helices (α_1(46–57) and α_2 (100–107)). The topology of the β-sheet in relation to the primary sequence is such that the five β-strands are arranged from the top to the bottom of the molecule thus: β_5 (residue numbers 89–97)↑, β_4 (77–87)↓, β_1 (10–19)↑, β_2 (29–35)↓, and β_3 (40–42)↑, where arrows indicate the polarity relationship between the polypeptide chains. The same β-sheet topology is seen elsewhere only as part of the variable region of immunoglobulin[25,26], in which the 30–40 β-strand corresponds to the β_1 strand of SSI.

According to Levitt and Chothia[27], SSI subunit belongs to the "class II" or "all β" type of proteins. Most of the non-crystallographic predictions[9] on the states of some specific amino acid residues have proved qualitatively correct. These include the nature of the peptide NH (refs 28,29), conformation of S–S bridges (M. Nakanishi, unpublished observation), and the states of tryptophyl[30,31], tyrosyl[30,32], histidyl[32,33], and methionyl residues[32]. Detailed evaluation of these results will be published elsewhere[22].

The subunit–subunit interface

The interface is formed by the stacking of a β-sheet of one subunit on top of a β-sheet of the other subunit, related by a diad. The planes of the two β-sheets are roughly parallel (Fig. 1*a*), whereas the β-strands in the opposite sheets are inclined at about 30° to each other (Fig. 1*b*). Similar stacking of β-sheets at the subunit–subunit interface has been previously reported only at the dimer–dimer interface of concanavalin[34] and in the monomer–monomer interface of glyceraldehyde-3-phosphate dehydrogenase related by the 'P' axis[35]. In the former case, the β-strands in the opposite sheets are inclined to each other in about the same way as in SSI, but in the latter case, they seem to

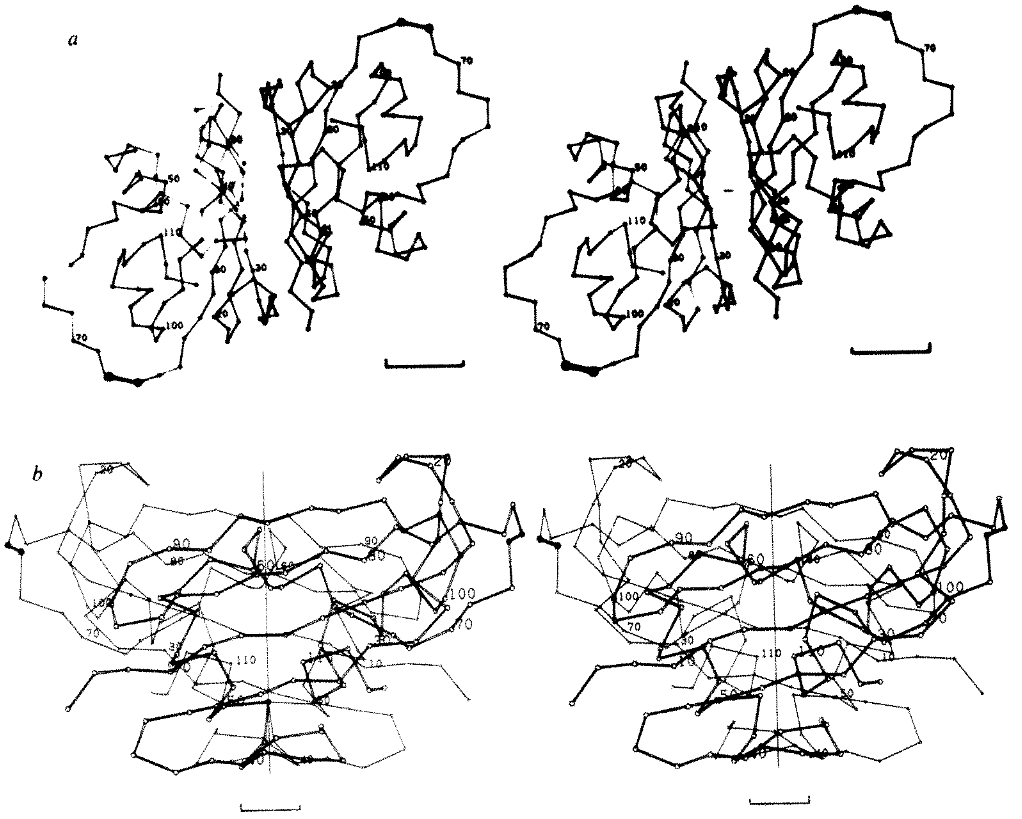

Fig. 1 α-Carbon chains of a SSI dimer viewed *a*, along the diad and, *b*, perpendicular to the diad. The reactive site Pl, Pl′ residues are marked. Scale bars represent 10 Å and 5 Å, respectively, for *a* and *b*.

run almost parallel. All the 48 intersubunit contacts of less than 3.8 Å, except for three possible hydrogen bonds, are non-polar in agreement with the observed susceptibility of the dimer to SDS (ref. 36). An interesting feature of the side chain packing in the interface is the straight side chain of Arg-90 held tightly in a pocket formed by Thr-15, Ala-22, Pro-27 and Leu-79 of the opposite subunit, and constituting an effective device for correct alignment of the subunits.

Of the 15 residues participating in the subunit–subunit interaction, only one replacement residue, Thr-34 to Asn, is seen in the closely related dimeric inhibitor, plasminostreptin (isolated from *Streptomyces antifibrinolyticus*)[37–39], which has 64% overall homology with SSI. This suggests that the purpose of the dimeric structure is the preservation of its own function and or stability. Inspection of the model shows that all the amino acid side chains replaced in plasminostreptin can be accomodated in the structure of SSI. SSI and plasminostreptin are, therefore, homologous proteins.

The reactive site and the C-terminal region

The electron density around the reactive site residues (Cys-71 to Tyr-75) is very high indicating the rigidity of this region as in BPTI[4] and STI[6]. The region seems to be tightly held by the β_4-strand embedded in the β-sheet and by the 71–101 disulphide bridge which, in turn, is fixed to the core of the subunit through helix α_2 and the C-terminal residues. The C-terminal four residues Val-110, Phe-111, Ala-112 and Phe-113 (the 111 and 112 order has been reversed (T. Ikenaka, personal communication)), can be selectively removed from intact SSI by treatment with carboxypeptidase A (M. Sakai, M. Odani & T. Ikenaka, in preparation). This derivative, SSI-A, still weakly inhibits subtilisin BPN′. However, the inhibition is only temporary if an excess of the enzyme is present. The normal inhibitory activity was almost completely recovered by adding a 30-fold excess of the C-terminal deca-, nona- or octapeptides to SSI-A. These observations, together with the UV difference

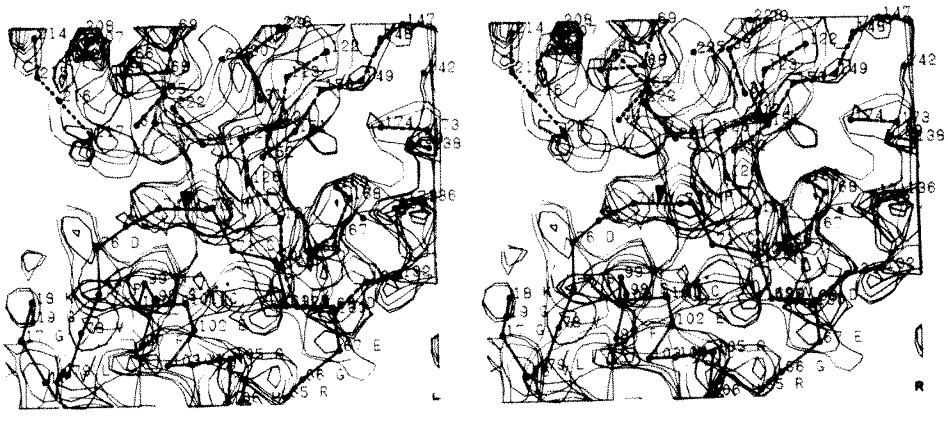

Fig. 2 α-Carbon chains of SSI (solid lines) and subtilisin BPN′ (broken lines) in the region of contact fitted into a 4.3-Å resolution electron density map of the SSI · subtilisin complex. The scissible bond is marked by ▼.

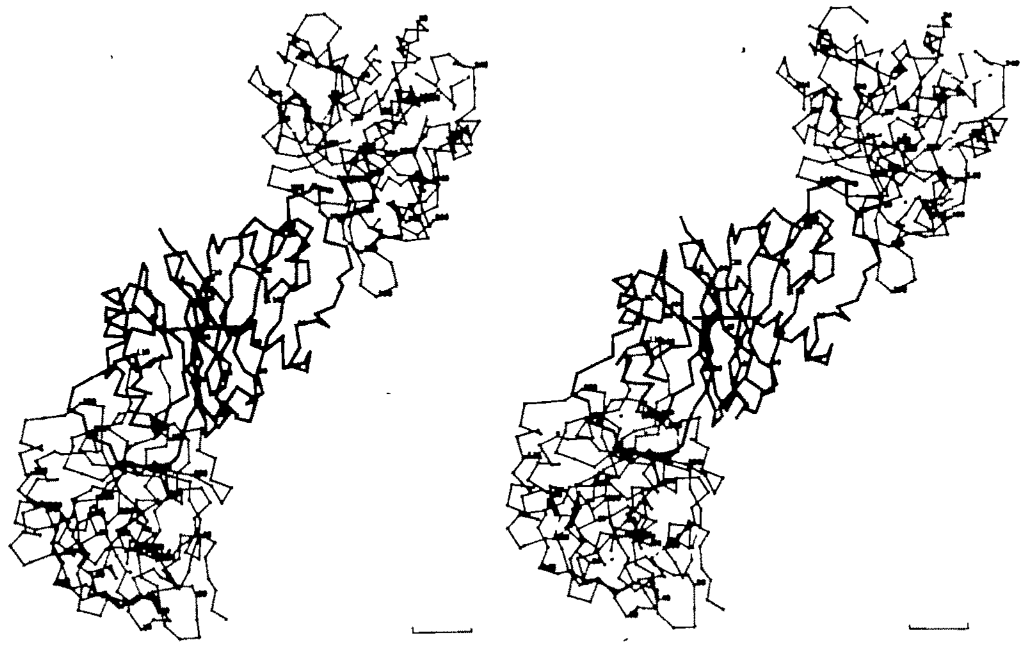

Fig. 3 α-Carbon chains of a complex of SSI dimer (solid bonds) with two subtilisin BPN′ (open bonds) The diad (horizontal line in the centre) is inclined to the plane of the paper at an angle of 60°. Scale bar represents 10 Å.

spectra, suggested that SSI-A has a somewhat loosened structure which is susceptible to proteolytic attack, but that the structure of intact SSI is almost fully restored on addition of the C-terminal oligopeptides. The C-terminal four residues make 43 inter-atomic contacts of less than 4 Å with the rest of the molecule, 93% of them being non-polar; this may explain the destabilisation of the molecule when they are removed.

Comparison of main-chain conformations of the reactive site residues and the substrate

Table 1 compares the main-chain torsion angles in the reactive sites of BPTI, STI, SSI and a hypothetical substrate[40] when bound to subtilisin BPN′. For BPTI and STI the values were obtained from the published refined coordinates[1,6]. The values for SSI, although not yet refined, are probably correct within 15°. The values for the substrate are based on provisional coordinates. Between BPTI and SSI, the angles for P_2, P_1, P'_1 and P'_2 agree within experimental error, despite the completely different amino acid sequences at the reactive site and the different proteinase specificity (BPTI does not inhibit subtilisin BPN′). For P_2 and P_1 the agreement extends to STI as well. The difference in P'_2 parameters between STI and SSI clearly reflects different chain conformation. The P'_1 parameters of STI present a problem. The combination of ϕ and ψ is energetically unfavourable, and Sweet *et al.*[6] noticed that, in the given orientation of the peptide bond between Ile-64′ and Arg-65′, there was no suitable hydrogen bond for NH(65′). Re-examination of the map shows that $\phi(P'_1)$ may well be $\sim 180°$ (J. Janin, personal communication). For P_3, the trypsin inhibitors do not share a common conformation with SSI. This reflects the fact that, in the trypsin inhibitors, P_4, P_5, ------ are not on the surface of the enzyme, but those in SSI are still on the surface.

Comparing SSI and the hypothetical substrate, the overall agreement (except for $\psi(P'_2)$) is clear, if allowances are made for the appreciably large errors in the latter coordinates. The difference in $\psi(P_1)$ and $\phi(P'_1)$ might be significant, but detailed study must await a high resolution map of the SSI · subtilisin complex. At the resolution now obtainable, there is no clear indication of any change in SSI conformation on complex formation. The structure of the hypothetical substrate was deduced from X-ray difference Fourier studies on the binding of various peptide chloromethyl ketones[41] and polypeptides[40] to subtilisin BPN′. Apparently because of weak P_1 specificity (compared to trypsin), the results were controversial. Despite these difficulties, the present comparison strongly suggests that the productive binding mode of substrates to subtilisin proposed

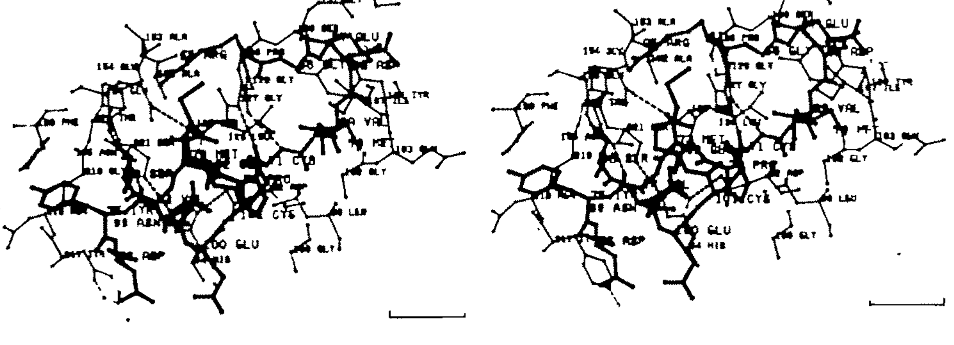

Fig. 4 The region of contact of a model of the SSI (in solid bonds and larger characters) and subtilisin BPN′ (in open bonds)[43] complex constructed as for Fig. 3. All residues relating to the intermolecular short contacts of less than 4 Å are shown The bonds for Arg-65′–Met-70′ are striped because the corresponding electron density in the SSI crystal is very weak. Scale bar represents 5 Å.

by Kraut *et al.*[40] is essentially correct and that, as in the case of trypsin inhibitors[3,6], the binding mode of a protein proteinase inhibitor (SSI) to subtilisin is, at least, closely related to that of substrates.

Comparison of overall conformation in BPTI, STI and SSI

The similar conformations of the reactive sites of the three inhibitors prompted us to investigate whether the similarity extends to any other part of the molecule. Despite the large difference in length (BPTI, STI and SSI have 58, 181 and (2×)113 residues, respectively) and apparent heterology in primary sequences, this seemed relevant, as three-dimensional structure is one of the properties which is probably most highly conserved during evolution. The coordinate systems of BPTI and STI were translated and rotated by a least-squares procedure to optimise the overlap between the corresponding main-chain atoms of the reactive site residues (P_2 to P'_2 for BPTI, P_2 to P'_1 for STI) and those of SSI. The general non-relatedness between SSI and BPTI (or STI) was clear, although there is some topological resemblance between residues 6–43 of BPTI and residues 60–103 of SSI (details will be published elsewhere)[22]. Most probably, the three inhibitors have evolved convergently from independent ancestral proteins, for the common purpose of inhibiting serine proteinases, and resulting in a similarity of the reactive site alone.

Table 1 Reactive site residues and main-chain conformations of BPTI[3], STI[6] and SSI

	P_3		P_2		P_1		P'_1		P'_2	
	ϕ	ψ	ϕ	ψ	ϕ	ψ	ϕ	ψ	ϕ	ψ
BPTI	−86	−28	−64	152	−116	87	−135	166	−116	87
STI	−46	−21	−77	136	−89	85	(−135)	(−115)	−175	−179
SSI	−123	141	−52	134	−92	89	−117	169	−120	78
Hypothetical substrate	(−157)	(172)	(−84)	(162)	(−116)	(26)	(−62)	(136)	(−112)	(−70)
BPTI	Pro		Cys		Lys(15)		Ala(16)		Arg	
STI	Ser		Tyr		Arg(63)		Ile(64)		Arg	
SSI	Cys		Pro		Met(73)		Val(74)		Tyr	
Hypothetical substrate	Ala		Ala		Tyr		Val		Val	

Corresponding data (in parentheses) for a hypothetical substrate[40] productively bound to subtilisin BPN′ are only provisional. Dihedral angles within 35° of the corresponding ones in SSI are outlined.

It is interesting that there are already three distinct patterns of 'protein proteinase inhibitor fold', and the number of such folds is likely to increase, as there are many examples (such as soybean Bowman–Birk inhibitor) of compounds whose structure cannot be similar to any of the known folds, because they have a different pattern of disulphide bridging[42]. In contrast, the serine proteinases, the target molecules, show only two basic patterns of chain folding, those of trypsin and subtilisin.

Structure of the complex molecule

The mixture (~1:2) of SSI and purified subtilisin BPN′(EC3.4.21.14) (Nagase, lot. 7370935) in 0.05 M Tris-HCl buffer (*p*H 7.5) was separated from excess inhibitors and autodigested enzymes by gel filtration. The crystals were easily obtained by leaving the main fractions in a cold room[16]. The structure was solved at 4.3 Å resolution using two heavy-atom derivatives, $(NH_4)_2Pt(NO_2)_4$ and K_2PtCl_4, for which the ratio r.m.s. heavy-atom structure factor/r.m.s. lack-of-closure error for the 3,550 independent reflections was 16.4/7.6 and 15.7/7.3, respectively, and of which details will be published elsewhere.

The model shown in Fig. 3 was first constructed using a rough correspondence in reactive site conformation between SSI and a hypothetical substrate (Table 1), and then adjusted by fitting it to the electron density through computer graphics (Fig. 2). At this resolution, there is no sign of major conformational change on complex formation in either SSI or subtilisin BPN′. As in the case of trypsin inhibitors[3,6], the region of contact is small: of the 113 and 275 amino acid residues, respectively, composing SSI subunit and subtilisin BPN′, only 11 and 19 residues are in contact. Recent estimation of the thermodynamic parameters of the complex formation using the temperature dependence of K_I yielded a value $\Delta H = +4.2$ kcal mol^{-1} and $\Delta S = +57$ e.u. (at 25°C, *p*H 7.0)[10], showing that the process is entropy driven as is the case for other trypsin inhibitors[5].

The SSI–subtilisin interface

Figure 4 was obtained by the same procedure as for Fig. 3. Because the parameters defining relative translation and orientation of the two molecules were adjusted with reference to the electron density map, the nature of the model is semi-empirical. The model is based on the coordinates determined for the crystals of SSI alone and subtilisin BPN′ alone[43,44]. Thus, in the actual structure, induced fit could cause movement of, for example, Tyr-104 of the enzyme (as observed in the difference Fourier studies[40,41] on subtilisin BPN′). As in trypsin inhibitors[3,6], the sequence of P_4 (Met-70′, (prime indicates the inhibitor)), P_3 (Cys-71′), P_2 (Pro-72′) and P_1 (Met-73′) makes an antiparallel β-sheet with the Ser-125–Gly-127 sequence of the enzyme. A possible scheme for hydrogen bonding is shown. Discussion of the nature of the interaction between the susceptible bond and the active serine (Ser-221) must await high resolution studies.

There are two kinds of interaction which differ from those made by trypsin inhibitors[3,6]. First, P_4 (Met-70′), P_6 (Asp-68′) and P_7 (Glu-67′) are still on the surface of the enzyme. Although the precise mode of interaction involving these residues cannot yet be considered because of their flexibility in the SSI crystal, the proximity of P_4 to Gly-102, Glu-103 and Tyr-104 and of P_6 and P_7 to Ser-130 is clear. In the complex crystals, the electron density for the region Glu-67′ to Met-70′ is comparable with that for other regions (Fig. 2). We may tentatively conclude that the flexible loop (Glu-67′–Met-70′) of SSI becomes fixed on complex formation with subtilisin BPN′. We suggest that the P_4 and the subsequent (to the N terminus) residues may be important for the interaction of substrates with subtilisin BPN′. Robertus *et al.*[40] suggested that the S_4 site has a strong affinity for the phenylalanine side chain and that the site might have an important role in determining the cleavage point for the polypeptide substrate. P'_3 (Asp-76′) and the subsequent (to the C terminus) residues, on the other hand, are not in contact with the enzyme.

The second unique interaction made by SSI is located along the polypeptide chain close to the reactive site, through the 71′–101′ disulphide bridge. In this region, Ser-98′ is close to Asn-155 and Glu-156, whereas Glu-102′ is close to Glu-156 (Fig. 4). Let us call this site of interaction the 'secondary contact region', as opposed to the 'primary contact region' which is related to the reactive site residues (Glu-67′–Tyr-75′). The interaction through the secondary contact region is also present in the complex of BPTI with trypsin[3,4]. In this case, the residues Gly-36′, Gly-37′ and Cys-38′, which are close to the reactive site through the 14–38 disulphide bridge, are on the surface of the enzyme. A hydrogen bond is present between the peptide carboxyl group of Gly-37′ and the phenolic hydroxyl group of Tyr-94 (ref. 3). However, optimal superposition of BPTI on SSI (mentioned above) shows that the stereochemical relationship of the secondary site to the primary site is completely different

The comparison is made for *a*, the primary contact region and *b*, the secondary contact region (see text). The Table is an extension of that made by Laskowski, Jr[48]. For the avian ovomucoids[48] frequencies of appearance are shown in parentheses. Somewhat arbitrary homology relationships T = S, P = F; R = K, V = L = I were assumed. The cystines corresponding to Cys-71 and Cys-101 of SSI are connected in all the inhibitors. Solid outlines are for homologies involving SSI and dotted outlines are for those involving plasminostreptin only.

for the two inhibitors[22]. In the case of STI, which has no disulphide bridge close to the reactive site, there cannot be a similar secondary contact region, although some interactions other than those at the primary site are present[6].

Relation to pancreatic secretory inhibitor

There is evidence for the close evolutionary relationship of pancreatic secretory (Kazal) trypsin inhibitors (PSTI)[45], acrosine inhibitors[46], canine submandibular inhibitors[47] and avian ovomucoids[48]. Let us provisionally call this 'family' of trypsin inhibitors the PSTI family. Moreoever, Ikenaka *et al.*[14] discovered a homology between SSI and PSTI. To a recent exhaustive list of the PSTI family made by Laskowski[48], data for SSI[14] and plasminostreptin[37] have been added (Table 2). In the reactive site (the primary contact region) the homology between the SSI sub-family (including plasminostreptin) and the PSTI family extends over 19 residues, ranging from Glu-67′ to Val-85′ of SSI. Another homologous region exists between Val-96′ and Glu-102′ of SSI[14]. In both the PSTI family and the SSI sub-family, the cystine corresponding to Cys-71′ of SSI is connected to that corresponding to Cys-101′ of SSI. Surprisingly, this second homologous region is exactly the same as the secondary contact region mentioned above. In SSI, the side chain of Glu-100′ is exposed to the solvent, making no contact with either subtilisin or other parts of SSI. Thus the frequent replacement of this residue by a lysine having opposite charge is understandable. Asn-99′, having no contact with subtilisin, seems to act as a spacer between the primary and secondary contact regions. The persistent conservation of this asparagine residue might reflect such a role. The replacement of this residue by histidine inactivates the inhibitor (Laskowski, personal communication).

Ser-98′ makes contacts with Asn-155 and Glu-156. The replacement of this residue seems to be mostly restricted to the residues with stereochemically similar side chains. The same restriction seems to apply to Glu-102′ the other residue making direct contact with subtilisin. The other highly conserved residues, Phe-97′ and Val-96′, make no contacts with subtilisin. However, Phe-97′ seems to have the important role of fixing the secondary contact region to the rest of the molecule, with its benzene ring being tightly held by Met-103′, His-106′ and Arg-95′. Based on these findings it is very tempting to conclude that the inhibitors of the SSI sub-family and those of PSTI family are evolutionarily related despite their large phylogenetic distances. The inhibitor from leech[49] (see Table 2) supports this hypothesis. However, before it can be confirmed, many more inhibitors from sources phylogenetically located between bacteria and mammals must be sequenced, and we plan a crystal structure analysis of a complex of PSTI with trypsin.

Origin of proteinase specificity

SSI strongly inhibits subtilisin BPN′ but only weakly inhibits α-chymotrypsin and trypsin[11,12]. BPTI and STI, on the other hand, strongly inhibit mammalian serine proteinases of the trypsin family but do not inhibit subtilisin BPN′ (ref. 1). Using the same principle as that used for preparing Fig. 3, a hypothetical complex of subtilisin with BPTI or STI can be generated. In the case of BPTI, there are serious overlaps of atoms around Cys-38′ of BPTI and around Gly-100 of subtilisin. Inspection of the model shows that these cannot be avoided by adjusting the relative orientation of the two molecules. The same situation exists for STI, where the overlaps are between atoms around His-71′ of STI and Ala-99 of subtilisin. The reason that BPTI and STI do not inhibit subtilisin BPN′ is simply due to the steric hindrance of atoms not belonging to the reactive site. In a complex of SSI with trypsin, on the other hand, there is no such obvious steric hindrance. The reason for weaker inhibition of trypsin[11] must lie in the reactive site itself. It should first be noted that P_1 of BPTI (Lys-15′) and STI (Arg-63′) form a strong ion pair with a carboxyl group (Asp-189) of trypsin[3,6]. For SSI having Met-73′ as P_1, the carboxyl group would constitute an isolated minus charge in the SSI · trypsin complex. In subtilisin BPN′, there is no charged group in the S_1 crevice[43], and the fit of the methionyl side chain seems ideal. Plasminostreptin with lysine as P_1 moderately inhibits both trypsin and subtilisin BPN′ ($K_\mathrm{I} \simeq 10^{-8}$M)[39]. Apart from P_1, we note that P_2' is arginine in both BPTI and STI. The guanidium ion has no complementary charge in the corresponding crevice of trypsin and, in this sense, tyrosine (in SSI) or phenylalanine (in plasminostreptin) might be more favourable. The P_2 residue has a bulky group in both BPTI (Cys-14′) and STI (Tyr-62′), but has only a moderately bulky group in SSI (Pro-72′) and plasminostreptin (Thr-68′). Recently, Fujiwara *et al.*[50] estimated K_I for the SSI · thiolsubtilisin complex to be 1.3×10^{-5} M at *p*H 7.0. The finding that the introduction of an atom with van der Waals radius larger only by 0.45 Å results in dramatic weakening of the association, suggests that the strong affinity between SSI and subtilisin BPN′ is highly dependent on the precise geometrical fit between the two molecules.

We thank Professors S. Murao, K. Hiromi and B. Tonomura and Dr S. Sato for support, and Professors M. Laskowski, Jr, J. Kraut, D. M. Blow and T. Ikenaka for providing unpublished data.

The *E. coli* gene encoding heat stable toxin is a bacterial transposon flanked by inverted repeats of IS*1*

Magdalene So, Fred Heffron & Brian J. McCarthy

Department of Biochemistry and Biophysics, University of California San Francisco, San Francisco, California 94143

Restriction endonuclease subclones of the Escherichia coli gene encoding the heat stable (ST) toxin exhibit a stem and loop structure similar to those seen in many procaryotic transposons. An EcoRI DNA fragment encoding tetracycline (Tc) resistance but no transposition functions was spliced into the ST gene in one of these subclones. By monitoring Tc^r, we were able to show that the ST gene transposes. Restriction and DNA sequence data strongly suggest that the ST transposon, Tn1681, is flanked by inverted repeats of IS1.

ENTEROTOXIGENIC *Escherichia coli* have been implicated in diarrhoeal disease of pigs, cattle, sheep and man[1–5]. Toxigenic strains of *E. coli* elaborate two types of toxins, one heat labile (LT) and the other heat stable (ST)[6,7]. Like cholera toxin, LT stimulates adenyl cyclase; moreover it is immunologically cross reactive with cholera antitoxin[8,9]. LT activity is assayed using either Chinese hamster ovary cells (CHO)[8] orY-1 adrenal mouse cells[10]. ST is small (less than 5,000 MW)[11,12], is nonimmunogenic and probably exerts its toxic effects via stimulation of guanylate cyclase[13,14]. ST activity is assayed in suckling mice[15]. The genetic determinants for both toxins are plasmid borne and can occur together on the same plasmid or separately[16,17]. We have reported the cloning of the gene which encodes the LT toxin as a DNA fragment of 3.0 kilobases[18] and the gene which encodes the ST toxin as a fragment of 8.9 kilobases[19]. We report here the subcloning of the ST determinant into restriction fragments ranging in size from 3.4 to 0.4 kilobases. Detailed study of one of these subclones revealed that the ST gene resides on a transposon flanked by inverted repeats of IS*1*.

Subcloning the ST gene

The construction of a plasmid hybrid (ESF3001) consisting of an 8.9 kilobase *Eco*RI fragment encoding the ST toxin cloned into RSF2124 (ref. 19) has been described. Cleavage of this fragment with *Bam*HI results in two fragments of approximately 5.6 and 3.4 kilobases (Fig. 1*a*). These two *Bam*HI–*Eco*RI fragments were cloned separately in pBR322 which had been cleaved with *Bam*HI and *Eco*RI. Removal of the internal *Bam*HI–*Eco*RI fragment from pBR322 results in a tetracycline sensitive (Tc^s) phenotype since the *Bam*HI site is within the Tc resistance gene[20]. Following transformation into *E. coli* RR1 (refs 20, 21), clones were selected for resistance to ampicillin (Ap) and then tested for sensitivity to Tc. The restriction pattern of plasmids from six clones exhibiting the Ap^r Tc^s phenotype were examined and found to contain either the 5.6 or 3.4 kilobase insert. Only the clones containing the 3.4 kilobase insert produced ST. One such clone was used for further study and was designated pMS2.

Digestion of the pMS2 insert with *Pst*I results in three fragments of 1.7, 1.4 and 0.3 kilobases (Fig. 1*a*). The central 1.7 kilobase *Pst*I fragment (Fig. 1*b*) was cloned in the *Pst*I site of pBR322. The single *Pst*I site within pBR322 occurs in a region encoding Ap resistance[20]. Transformants were therefore selected for Tc^r and checked for sensitivity to Ap. Tc^r Ap^s clones contained the 1.7 kilobase insert and produced ST. One such clone was used for further study and was designated pMS3.

Characterisation of the ST clones

Examination of single-stranded DNA from the ESF3001 plasmid which contains the *Eco*RI ST$^+$ fragment in the electron microscope[22] reveals the presence of a prominent inverted repeat (double-stranded segment) flanking a shorter single-stranded region (Fig. 2*a*). Measurement of this double-stranded segment relative to native relaxed pSC101 DNA (9.4 kilobase) included in the same grid places the size of the inverted repeat at 760 base pairs. Examination of the *Bam*HI–*Eco*RI and the *Pst*I fragments shows that the inverted repeat is present in these inserts (Fig. 2*b*, *c*). The *Pst*I sites are apparently within the inverted repeat since the double-stranded portion of the single stranded *Pst*I fragment is shorter than the original length by approximately 180 base pairs.

Figure 1*b* shows a restriction map of the pMS3 insert. Since the *Pst*I fragment has an inverted repeat (IR), restriction sites within the IR would be symmetrically arranged and digestion with these restriction enzymes would yield two DNA fragments of identical molecular weight. Digestion of the *Pst*I fragment with *Alu*I yields fragments of 392 base pairs (two fragments), 102 base pairs (two fragments), 350 and 290 base pairs, when calibrated with *Hin*cII fragments of ΦX174 RFI DNA[23]. The *Alu*I sites giving rise to the largest and the smallest fragments would therefore lie within the IR.

Many antibiotic resistance determinants are known to be transposable; they lie in discrete regions of DNA bounded by inverted repeated sequences (see ref. 24 for review). The cloned fragments of DNA containing the ST gene exhibit strikingly similar morphology. By analogy to known transposable genetic determinants, the ST gene would be expected to lie within the area comprising the loop in the stem and loop structure visualised in the electron microscope. Referring to the map (Fig. 1) the site would be located within the area delineated by the two middle *Alu*I fragments. These two *Alu*I fragments were purified and cloned separately in the *Hin*dIII site of pBR322. Since DNA cleaved with *Alu*I contains duplex or 'flush' ends, the *Alu*I fragments were ligated to synthetic decameric oligodeoxynucleotides, or 'linkers', encoding the restriction site for *Hin*dIII[25]. Neither *Alu*I fragments thus cloned gave rise to an ST$^+$ phenotype. In the same experiment we also cloned the 113 base pair *Alu*I fragment. These clones were also ST$^-$.

In a separate experiment a partial *Alu*I digest of the *Pst*I fragment produced a double *Alu*I fragment consisting of the 350 and 290 base pair fragments. This *Alu*I double fragment was subsequently purified and cloned into pBR322 again using the *Hin*dIII linkers. Clones containing this 640 base pair fragment were ST$^+$. It thus seems that the middle *Alu*I site is within an

0028–0836/79/0277—0453$01 00

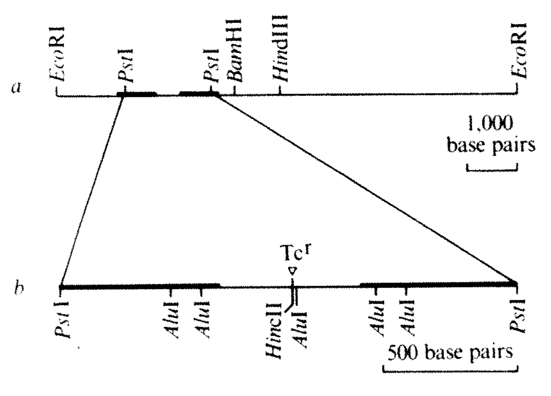

Fig. 1 Restriction maps of *a*, the 8.9 kilobase ESF3001 *Eco*RI insert and *b*, the 1.7 kilobase pMS3 *Pst*I insert. Restriction enzyme analyses of DNA fragments were performed in conditions recommended by the suppliers. *Alu*I, *Bam*HI and *Hin*cII were obtained from New England Biolabs; *Hin*dIII from Boerhinger-Mannheim. *Pst*I and *Eco*RI were purified in the laboratory according to the procedure of Greene[42]. DNA fragments were electrophoresed in 0.8% agarose in Tris-borate buffer[41], with *Eco*RI fragments of λ phage as molecular markers; or in 7% acrylamide in Tris-borate buffer, with *Hin*cII fragments of ΦX174 RFI DNA as markers[23]. *Alu*I sites were not mapped beyond the 1.7 kilobase *Pst*I fragment.

area essential for ST expression. Plasmids containing this fragment are termed pMS6.

Restriction analysis of the pMS2 insert has already shown that there is a *Hin*cII site close to the centre of the fragment within 50 base pairs of the middle *Alu*I site. To determine if this *Hin*cII site is also necessary for ST expression, we mutated the site by ligating into it the *Hin*dIII linkers. There are three *Hin*cII sites within pMS2, two of them within pBR322 (ref. 20). pMS2 plasmid DNA was digested with *Hin*cII in conditions which allowed on the average one cleavage per molecule, so that the majority of the DNA consists of unit-length linear molecules. Kinase-treated *Hin*dIII linkers were added at a molar ratio of decamer to plasmid of 25 : 1, and ligated with T4 polynucleotide ligase. The DNA was restricted with *Hin*dIII to generate cohesive termini and the preparation electrophoresed through an acrylamide gel. Unit-length linear DNA was extracted from the acrylamide, circularised with *E. coli* DNA ligase and used to transform *E. coli* RR1. Transformants were selected for Apʳ and the plasmid DNA analysed for the location of the new *Hin*dIII site. Plasmids containing the *Hin*dIII insertion at the location of the former *Hin*cII site had the ST⁻ phenotype. These plasmids were designated pMS2a.

Identification of the inverted repeats flanking the ST gene

Several lines of evidence strongly suggest that the inverted repeat flanking the ST gene sequence is IS*1*. The estimated size of the ST inverted repeat (760 base pairs) is similar to that given by Ohtsubo for IS*1* (768 base pairs) (ref. 26). In addition, Ohtsubo reported that in IS*1* there are two *Alu*I sites within the region delineated by the *Pst*I site and the right hand end of IS*1*. The sizes of these fragments are (*Pst*I–*Alu*I) 407 base pairs, (*Alu*I–*Alu*I) 113 base pairs, and (*Alu*I–end of right end) 66 base pairs; these values agree well with those estimated for the corresponding fragments of the ST inverted repeat: (*Pst*I–*Alu*I) 392 base pairs, (*Alu*I–*Alu*I) 102 base pairs and (*Alu*I–end of ST IR) 66 base pairs.

The nucleotide sequence of the pMS6 insert was determined using the Maxam and Gilbert procedure[27]; the complete sequence will be reported elsewhere. The first and last 66 bases of the sequence are inversely repeated relative to each other. The top line of Fig. 3 shows the first 70 bases of the sequence. The first and last 66 bases comprise the end of the inverted repeat proximal to the loop as seen in the electron micrographs; comparison of the sequence with the last 66 bases of the right hand end of IS*1* (ref. 27) (bottom line) show that the sequences are identical; thus, we conclude that the ST gene is flanked by inverted repeats of IS*1*.

Transposability of the ST gene

The lack of a direct method of selection for the ST gene has hampered efforts to test for its transposability. However, the restriction sites within an area essential for ST expression provided a means to test this possibility. Antibiotic resistance genes can be inserted into that region and the resistance marker used to monitor transposability and to measure the frequency of transposition. For these experiments, pMS2 was used because it contains the entire inverted repeat. Octameric linkers containing the recognition sequence for *Eco*RI was ligated into the *Hin*cII site of the *Bam*HI–*Eco*RI insert as described above. A 2.4 kilobase *Eco*RI fragment encoding resistance to Tc but specifying no transposition functions was ligated into the newly generated *Eco*RI site. This fragment was originally cloned out of pBR322 using *Eco*RI linkers[28]. As the cloning vehicle retains a portion of its own tetracycline resistance genes, the resultant hybrid was transformed into the recA strain MV12(RSF2001) to preclude recombination with the newly introduced Tcʳ genes. RSF2001 is a kanamycin resistant derivative of F (ref. 29). Transformants were selected for resistance to Tc and plasmid DNA from these clones were examined for the presence of the *Eco*RI–Tcʳ fragment. One clone containing this fragment was used for the transposition studies and is designated pMS2b.

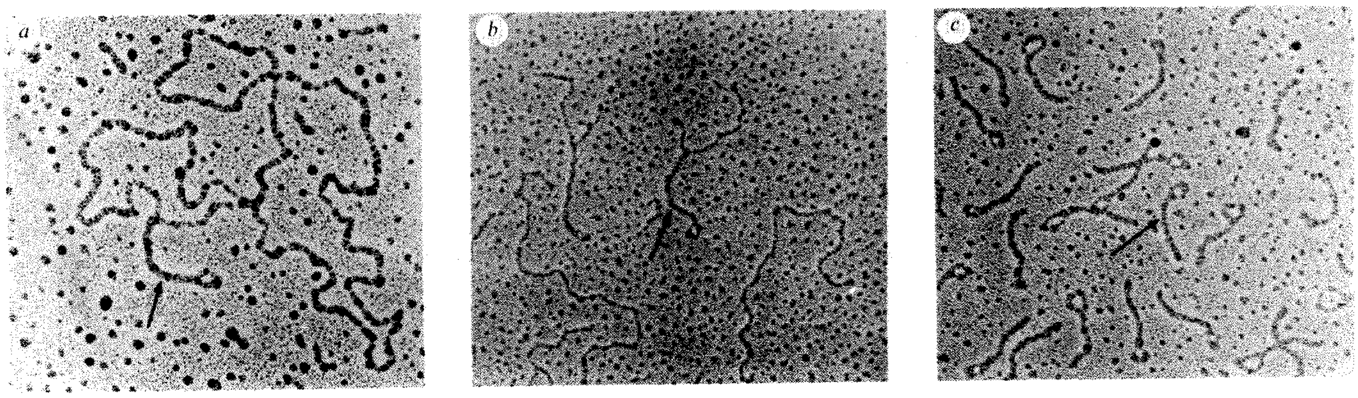

Fig. 2 Electron micrographs of single stranded DNA of *a*, ESF3001 plasmid; *b*, the 3.4 kilobase pMS2 *Bam*HI–*Eco*RI fragment; *c*, the 1.4 kilobase PMS3 *Pst*I fragment. Preparations of single stranded DNA fragments for microscopy were obtained by the procedure of Davis[22], and were examined using a JEOL 100B or a Philips 301. Micrographs in (*b*) and (*c*) were taken at the same (28,000) magnification.

Fig. 3 Nucleotide sequence of (top line) the first 70 bases of the pMS6 insert encoding ST, and (bottom line) the last 76 bases of the right hand end of IS*1* (as published by Ohtsubo[26]). The nucleotide sequence of the pMS6 insert was determined as described by Maxam and Gilbert[27]. DNA fragments ^{32}P-labelled at one 5′ terminus were obtained either by cleavage of the labelled fragment with a restriction enzyme or by strand separation[27].

A method for the detection of transposition of an antibiotic resistance gene from a ColE1 type plasmid has been described previously[29]. ColE1 has a strict dependence on the polI function of *E. coli*[30] while F-type plasmids do not. The strain MV12(RSF2001, pMS2b) was mated in 2.0 ml L broth with the nalidixic acid resistant (Nx^r) polI strain SF800 (ref. 29) at a donor to recipient ratio of 1:3. After 1 h of gentle shaking at 37 °C cells were plated on fresh MacConkey agar containing 20 μg ml^{-1} Nx, 5 μg ml^{-1} Tc. Since pMS2b is a ColE1 derivative, it cannot be maintained in SF800; Tc^r transconjugants arise only on transposition of the *Eco*R1–Tc^r fragment from pMS2b to the plasmid RSF2001 and the subsequent conjugal transfer of RSF2001Tc^r to SF800. Nx^{r}Tc^r clones were observed in three separate mating experiments. Six of these clones were isolated and all were able to retransfer Tc^r and Kan^r together in subsequent 1-h matings with HB101 or RR1 as recipients. The frequency of transposition of the *Eco*RI–Tc^r fragment by the ST transposon, expressed relative to the frequency of RSF2001 transfer to SF800, is $\sim 4\times10^{-6}$. In the same experiments, MV12(ESF2001,pBR322) yielded Nx^{r}Tc^r transconjugants in frequencies of $<0.01\times10^{-6}$ when crossed with SF800.

We examined 20 of these Tc^{r}Kan^r exconjugant clones from the MV12(RSF2001,pMS2b) × W3110 matings and found them to be also Ap^r and colicin immune indicating that the RSF2001 recipient plasmid contains the ColE1 portion of the pMS2b genome in addition to the ST gene. This event is IS*1* mediated and is recA independent. These observations are analogous to those of Jeffrey Miller (person communication) on Tn9, a transposon flanked by direct repeats of IS*1* (ref. 31). Using the same detection system he observes that transposition of Tn9 from a ColE1 derivative onto F results in plasmid cointegrates in which two complete copies of Tn9 have inserted into F as direct repeats flanking ColE1. Our preliminary results suggest the same sequence organisation in the recipient plasmid. In view of the observation that the transconjugants are in fact plasmid cointegrates it can be argued that the ST gene is not a true transposon. However, in rec$^+$ conditions the flanking direct repeats of the ST sequences recombine, leaving only a single copy of the ST transposon on RSF2001. Thus the end product is identical to a transposition event and it would be difficult to argue that transposition does not normally occur with such a transitory intermediate. In fact, transposition of certain mutants of Tn3 onto RSF2001 results in cointegrate plasmids with an identical sequence arrangement (Tn3–ColE1–Tn3) (ref. 32). Perhaps we are observing in these Tn3 mutants what would normally be an intermediate in the transposition process.

Discussion

Many plasmid mediated bacterial genetic determinants are known to be on transposons. They were first characterised in genes specifying antibiotic resistance in *E. coli* and *Salmonella* (see ref. 24 for review). More recently, transposons have been described in *Pseudomonas* specifying enzymes involved in resistance to mercuric ions[33] and in the degradation of toluenes and xylenes[34], and in *Yersinia* specifying enzymes for the utilisation of lactose[35]. To our knowledge the ST gene is the first pathogenic determinant shown to be on a transposon.

Most transposons are flanked by repeated sequences whose identities have yet to be established. Tn10 is reported to be flanked by inverted repeats of IS*3* (ref. 31) while in the case of Tn9 the chloramphenicol resistance (Cm^r) genes are flanked by direct repeats of IS*1* (ref. 36). Direct repeats of IS*1* have also been found on several R factors of the fi$^+$ class bracketing the resistance determinants (see ref. 37 for review). The ST transposon is the first instance in which the ends are flanked by inverted repeats of IS*1*. That IS*1* can occur in both orientations suggests that the directionality of IS*1* is not an important factor in transposition. On the other hand, Ohtsubo has reported the presence of short terminal inverted repeats within the IS*1* sequence itself; thus regardless of the orientation of the two IS*1*, the intervening genes still would be flanked by inverted repeats. And it is these internal inverted repeats which may play an essential role in transposition.

Transposable elements known to date confer easily detectable phenotypes. This, in fact, is how their transposability was first observed. Many other genetic determinants are not as amenable to such analysis because, like ST, their detection is difficult. Splicing an antibiotic resistance marker into such a gene to monitor transposition is a useful general strategy in such cases. The transposability of the ST gene accounts for the heterogeneity of the ST plasmids, which differ in their molecular size, %G+C content and incompatibility grouping[38]. A *Pst*I fragment of similar molecular weight encoding the ST toxin has been cloned from an *E. coli* enteropathogenic for pigs (N. Harford, personal communication). It would not be surprising then if the ST toxins elaborated by *E. coli* strains are closely related if not identical proteins.

Simple acquisition of an ST plasmid does not render an *E. coli* pathogenic. Besides producing ST, a strain must also elaborate an adherence or colonisation factor (CF) before it can become fully pathogenic[1,2,39,40]. Such factors are plasmid encoded and are cell and animal specific. The colonisation factor is expressed as filamentous cell surface proteins which enable the organism to adhere to the mucosa of the upper bowels of the animals, an area normally devoid of such organisms. In addition, diarrhoeagenic *E. coli* isolated from pigs elaborate a CF different from those isolated from calves or man. In the course of association between an ST and a CF plasmid within a pathogenic *E. coli* one would expect the eventual acquisition of the ST gene by a CF plasmid. Indeed such a case has been found. A plasmid encoding the human colonisation factor has been shown to harbour the ST gene as well (P. Shipley, personal communication).

Other pathogenic determinants such as the heat labile (LT) toxin and the K antigens may also reside on transposons. Silva *et al.* have reported the presence of inverted repeats bounding an area known to contain genes for both the ST and the LT in a plasmid isolate of an enteropathogenic *E. coli*[41]. Transposition has proved to be an important mechanism in the dissemination of antibiotic resistance; it may ultimately prove to be as common a mechanism as conjugation and phage conversion by which pathogenic determinants are acquired by bacterial genomes.

Death throes of massive stars

MASSIVE stars undergo violent deaths, forming the type II supernovae believed to result from gravitational collapse of the stellar cores. Such an event may be recognised by the optical outburst which occurs when the thermal and kinetic energy generated by the collapse propagates to the stellar photosphere. This occurs ~5–20 d after the collapse[1]. However, the optical data are incomplete in the sense that supernovae are invariably discovered at or shortly after peak optical intensity so only the decline from maximum brightness has been recorded in any detail. In addition, various theoretical models suggest that the optical radiation will be preceded by bursts of other forms of energy (neutrinos, gravitational waves, γ and X rays). Detection of these bursts, as well as of the early part of the optical light curve, would be greatly facilitated if the occurrence of a supernova could be predicted on the basis of the pre-supernova behaviour of the star. We show here that neutrino emission in the final stages of nuclear burning (as originally proposed by Morrison[2]) could, in principle, provide such a warning, though the current practical limitations are severe.

Our results are based on a study of the final stages of evolution of a $15M_\odot$ star (details will be published elsewhere). The evolution through hydrogen, helium, and carbon burning was computed with a hydrostatic stellar evolution code[3]. The subsequent stages (neon, oxygen, and silicon burning) were followed with an implicit hydrodynamic code[4]. The nuclear reaction network included the species ^{1}H, ^{4}He, ^{12}C, ^{16}O, ^{20}Ne, ^{24}Mg, ^{28}Si, ^{32}S, ^{36}Ar, and ^{56}Fe. Neutrino emission was computed according to the rates of Beaudet *et al.*[5] which include the pair-, photo-, and plasma-neutrino processes. The Weinberg–Salam model for weak interactions suggests that these rates should be revised upwards[6], but experimental evidence[7] indicates that the correction is less than a factor of 2. All of these processes produce equal numbers of (electron) neutrinos and antineutrinos.

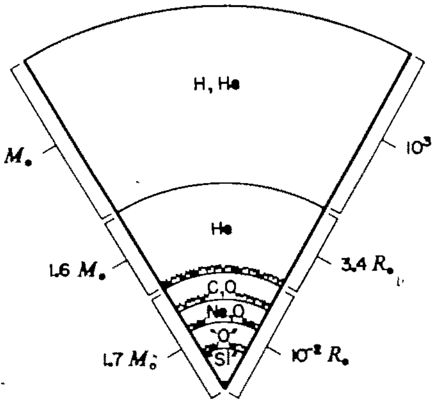

Fig. 1 Cross-section (not to scale) of the star at the beginning of the silicon-burning phase. Jagged lines indicate active burning regions. The composition of the O and Si zones consist of a number of species; 95% of the mass in the inner (1.7 $M_\odot$) region is contained in the Si zone.

The structure of the star at the start of the period of intense neutrino emission is shown in Fig. 1. This represents the beginning of the core-silicon-burning phase. The results of the calculations for the subsequent evolution are shown in Fig. 2, in which nuclear burning and neutrino energy emission rates are plotted against time. Average neutrino energies at representative times are also indicated. As the dominant neutrino emission process is the destruction of electron–positron pairs, the neutrino energies include the 0.511 MeV rest-mass energy of the annihilated particles. The first (broad) peak in neutrino emission represents core silicon burning, which occurs several months before collapse, and subsequent (sharp) peaks are due to increasingly violent shell flashes. The last major burst corresponds to a silicon flash ~4 d before collapse. We should emphasise that, although the nuclear energy generation rate varies by 7 orders of magnitude during this period, no detectable variations in the surface photon luminosity occur. To an optical observer, the star appears as a perfectly normal red supergiant and gives no warning of the impending explosion.

To examine the detectability of the predicted fluxes, the background levels over which the stellar neutrinos (or antineutrinos) must dominate should be considered. For this purpose we choose the last peak, at which time the neutrino (plus antineutrino) luminosity is $6\times10^{11}L_\odot$ and the average energy per particle is 0.83 MeV. For the neutrinos, the main background is the Sun. Optimal discrimination against solar neutrinos is afforded by a detector which is insensitive to the copious p–p neutrinos, such as the ^{37}Cl experiment of Davis[8]. The condition that the capture rate for stellar neutrinos be greater than for solar neutrinos is

$$\sigma_\nu F_{\nu *} > \Sigma\sigma_\odot F_{\nu\odot} = 1.6\times10^{-36}\ \mathrm{s}^{-1} \qquad (1)$$

where we have used the measured value for the solar neutrino capture rate[9]. With $\sigma_\nu = 2.4\times10^{-46}$ cm^2, we find that the pre-supernova object would have to be within 34 pc to be detected. Obviously this is unacceptable. Note that Bahcall[10] has estimated that the neutrino burst due to core collapse would be detectable at a distance of 4.5 kpc. However, radiochemical detectors are generally not very suitable for supernova prediction as they involve long integration times and give no directional information.

The situation is more favourable for the antineutrinos, where the solar background is negligible and the main background is

0028-0836/79/0277—0456$01.00

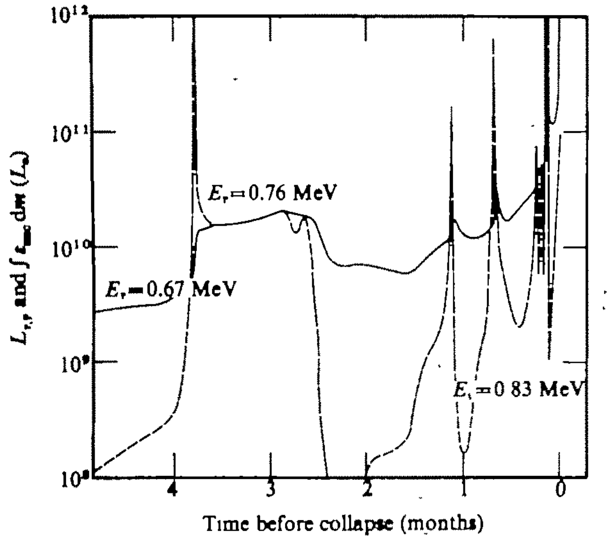

Fig. 2 Total energy emission due to neutrino pairs (solid line) and energy generation by nuclear reactions (dashed line) as functions of time. Average neutrino energies are indicated at various points. The $E_\nu = 0.83$ MeV notation refers specifically to the last silicon flash.

due to radioactive decays in the Earth's crust. The flux of terrestrial antineutrinos is not well known, but it is estimated to be $F_{\bar{\nu}\oplus} \sim 3.5 \times 10^6$ cm^{-2} s^{-1}, if we eliminate the decays with peak energies below 0.5 MeV[11]. As the remaining decays yield energies comparable to the expected stellar antineutrino energies, we can directly compare fluxes, without referring to cross-sections for a particular detector. The condition $F_{\bar{\nu}} > F_{\bar{\nu}\oplus}$ now leads to a distance limit of 1.5 kpc. With an expected event rate of ~0.1 supernova yr^{-1} in the entire Galaxy, this is not very encouraging. If we wish to monitor the entire Galaxy, a space experiment would be necessary. For a satellite in geosynchronous orbit, the terrestrial antineutrino background would be negligible, although the technical difficulties involved in designing a suitably sensitive detector should not be underestimated.

Antineutrinos emitted by massive stars in the final stages of nuclear burning could then be used to predict supernovae, though major improvements in detection techniques would be required. Note that the results presented above apply to a particular stellar mass (15 $M_{\odot}$) and that other masses might give substantially higher fluxes.

An ultraviolet spectrum of the high redshift quasar Q2204 – 408

AN ultraviolet spectrum of the radio-quiet quasar Q2204 – 408, redshift $z = 3.18$ (ref. 1), detected with the International Ultraviolet Explorer (IUE) is reported here. The object was selected for observation because of its high Lyman-α flux and the absence of a cut-off at the Lyman limit. The spectrum was obtained on 9 August 1978 with the short wavelength spectrograph which covers the range 1,150–1,950 Å (ref. 2). A finder field for Q2204 – 408 has been given by Osmer and Smith[1] and as the quasar is too faint ($m_v = 17.5$) to be detected by the fine error sensor of IUE, a blind off-set technique was used to image the quasar in the large (10 × 20 arc s) aperture of the short wavelength spectrograph. A very faint continuous spectrum of average signal ~5 DN above a background of ~60 DN was detected after an exposure of 350 min. (DN stands for data number and 256 DN gives full scale.) An emission feature is also probably present at 1,270 Å (304 Å in the rest frame of the source).

A computer program was developed to track the spectrum in both the raw and the photometrically corrected images. The data, in a strip 18 pixels wide and centred on the spectrum, were extracted without rebinning and only wavelengths longer than the night-sky Lyman α line have been considered. The data in the photometrically corrected image were compared with those in the raw image, and a visual examination made of the photowrite of the raw image so as to identify and remove signals caused by cosmic ray events and other noise spikes. The data in the central 6-pixel wide strip were combined and a background correction made by subtracting the smoothed signal on either side, thus giving the net spectrum. The signals were converted to absolute fluxes with the most recent[3] absolute efficiency of the short wavelength spectrograph. A scaling factor was used to convert the flux value obtained with the data extracting procedure used here to that which would be obtained with the extraction procedure used to derive the absolute efficiency of the spectrograph. This was determined to be ~1.2 by reducing the spectrum of the quasar MKN205 (also observed by us) with the two extracting procedures, and comparing the outputs.

The spectrum of Q2204 – 408 was averaged in 100 Å bands and the resulting fluxes and central wavelengths are given in Table 1. The r.m.s. errors are also given and the increase at the longer wavelengths is due to a high local background that was accumulated during the long exposure. The data between 1,400 and 1,500 Å have not been used, as they lie in a sensitivity minimum of the instrument (caused by the photocathode in the camera) where the signal becomes too low to be significant. Because of the large errors, the UV data have been combined to give the weighted mean listed in Table 1, where the error has been increased to allow for the uncertainty of ~10% in the absolute calibration[3]. The UV flux can now be compared with the visible flux measurement of Osmer and Smith[1] also given in the Table.

Table 1 Fluxes and central wavelengths for Q2204 – 408

Wavelength (Å) Rest frame of observer	Flux (10^{-16} erg cm^{-2} s^{-1} Å^{-1})	Wavelength (Å) Rest frame of source
1,350	4.2 ± 1.0	323
1,650	10.4 ± 1.4	395
1,750	9.9 ± 4.9	419
1,850	5.5 ± 3.4	442
1,480*	6.3 ± 1.0	354
6,165†	2.9	1,475

*UV weighted mean.
†From Osmer and Smith[1].

As usual, we assume a continuum flux distribution in frequency terms of the form $f(\nu)\alpha\nu^{-\alpha}$ and from the UV and visible data derive a value for the spectral index $\alpha = 1.5 \pm 0.3$. This is in the range found for quasars from optical and radio data and shows that the non-thermal continuum extends to wavelengths as short as ~300 Å in the rest frame of the source. It also confirms the great transparency of the intergalactic medium which has been well established by several workers (see, for example, refs 4, 5). A difference here is that the observed flux has been subjected to the full absorption characteristics of neutral hydrogen, that is, in the Lyman continuum and Lyman series, and this occurs in a local epoch ($z < 1$). Additionally, the flux will suffer absorption by any intergalactic neutral helium in the early epoch $z \sim 2$–3.

The extracted spectrum shows an emission feature near 1,270 Å which is probably real. Its wavelength is uncertain because the only internal standard is provided by the night-sky Lyman α line whose signal is saturated. However, the wavelength is clearly close to 304 Å in the rest frame of the quasar and the feature is likely to be the redshifted HeII resonance line. Its total intensity is estimated as $\sim 2 \times 10^{-14}$ erg cm^{-2} s^{-1} which can be compared with the intensity of (Lyman α + NV) = 11×10^{-14} erg cm^{-2} s^{-1} given by Osmer and Smith[1]. Further observations are being made which should confirm the reality of the feature.

The observations were carried out during UK time awarded by the SRC at the ESA Ground Station near Madrid. We acknowledge the support of Dr A. Heck and Mr F. Pevar during observations, and of Dr N. Argue in measuring off-sets.

The August 1972 solar proton event and the atmospheric ozone layer

OXIDES of nitrogen are generally accepted to be important for regulating the atmospheric ozone content through catalytic reactions first described by Crutzen[1] and Johnston[2]. In the stratosphere, nitric oxide is produced naturally by the reaction of nitrous oxide, emanating from the biosphere, with excited oxygen atoms generated by ozone photolysis at wavelengths shorter than about 310 nm. As Crutzen *et al.*[3] have pointed out, large amounts of nitric oxide may also be produced by high-energy solar protons, mainly at geomagnetic latitudes greater than 60°, and altitudes above about 35 km. The ozone measurements reported here made during an intense solar proton event in August 1972 suggest that NO production rates due to ionising particles are higher than those calculated by Crutzen *et al.*

This process of NO production is likely to occur in several steps: nitrogen molecules are ionised and dissociated by secondary electrons with energies in the range of tens to hundreds of electron volts. The subsequent reaction $N + O_2 \rightarrow NO + O$ is slow and temperature dependent for ground N (^{4}S) atoms, but not for electronically excited N (^{2}D or ^{2}P) atoms. As the electronic states of the N atoms were not known, Crutzen *et al.*, in their computation of NO production rates for three major solar proton events, considered two extreme situations with either complete or no production of N atoms in the excited states.

Recent rocket measurements of mesospheric and thermospheric nitric oxide concentrations revealed strong enhancements during auroral particle precipitation events (ref. 4 and F. Arnold, personal communication). From these measurements, and simultaneous measurements of ionisation rates, it is inferred that the NO-production rate is about 2–2.5 times the ionisation rate, while Crutzen *et al.* base their estimates on 1.5 mol per ion pair, as given by Winters[5]. These values imply that most of the N-atoms resulting from electron impact dissociation of N_2 are probably in an electronically excited state[4].

On 4 August 1972 a solar proton event occurred that was the most intense of any recorded within the past 25 yr. Ozone measurements made with the BUV experiment aboard the Nimbus 4 satellite during that period were the first ever to show unambiguously a decrease in stratospheric ozone due to a solar proton event[6]. Figure 1 shows total ozone amounts above the 4 mbar level, for three latitude belts, as published by Heath *et al.*[6]. Zonally averaged daily values are plotted with the respective error bars for the months of July and August 1972. In the polar region, between 75° and 80° N, the event produced an abrupt decrease in ozone above 4 mbar, of about 0.002 atm cm or 16%, which apparently persisted throughout the month of August. At latitudes between 55 and 65° N a very sharp drop was noticed 2 d after the event followed by a slow decrease of 5% within 8 d, and a gradual 'recovery' thereafter. Heath *et al.* interpreted this behaviour as being due to the advection of modified air from the source region, which is symmetric in geomagnetic coordinates by geographically orientated zonal motions, with the succeeding 'recovery' being similar to the seasonal changes found in other years in this latitude range. The

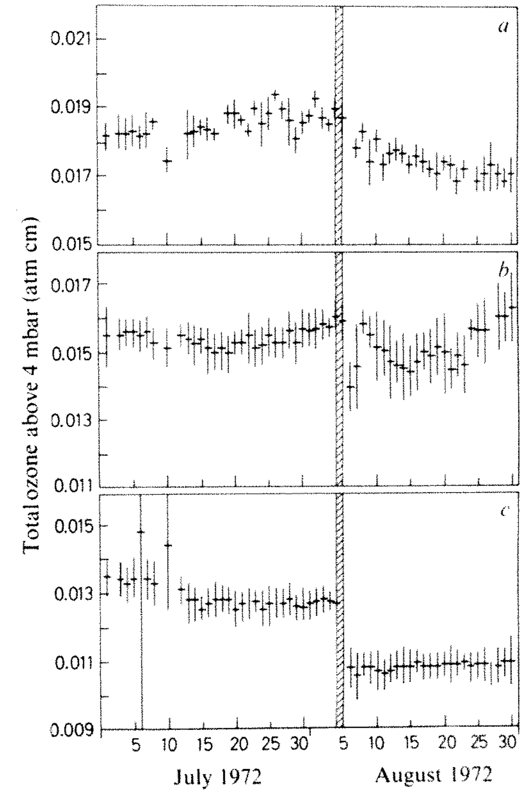

Fig. 1 Zonally averaged total O_3, above the 4-mbar pressure surface for equatorial (*a*), middle (*b*), and high latitudes (*c*) during July and August 1972. The solar proton event occurred on 4 August. After Heath *et al.*[6].

0028-0836/79/0277—0458$01.00

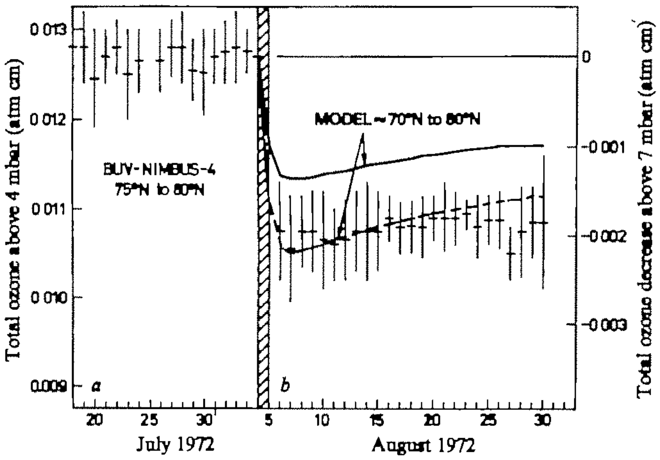

Fig. 2 Comparison of BUV–NIMBUS-4 ozone data (*a*) with model prediction for high latitudes (*b*). The model results are plotted as relative depletions with respect to the 'undisturbed' level on 4 August, before the event occurred. The solid line bases on NO production rates as given by Crutzen *et al.*[3]. The dashed line includes Arnold's modification[4].

ozone measured in the tropics are, although different from those observed in earlier years, not related uniquely to the proton event. According to Heath *et al.* the slow ozone increase during July and the steeper decline in August are likely to be partly due to an abnormal temperature decrease in July associated with a Southern Hemisphere stratospheric warming, followed by a recovery in August.

As Crutzen *et al.*[3] pointed out, studies of the ozone distribution in the stratosphere in periods following certain proton events, may be important for validating numerical models of photochemistry and transport processes in the stratosphere. We have performed such modelling experiments using the Oxford zonally averaged, two-dimensional model, described in detail by Harwood and Pyle[7]. This time-dependent model extends from the South Pole to the North Pole, with 19 latitude belts of slightly less than 10° width, and from the Earth's surface to about 80 km altitude, with a height increment of about 3.5 km (0.5 pressure scale heights). Eddy fluxes of heat and matter are treated using large-scale diffusion coefficients, while the momentum fluxes are specified from temperature measurements made mainly by the selective chopper radiometer on the Nimbus 5 spacecraft. Radiative processes, such as the absorption of solar radiation by ozone and the radiative cooling due to the CO_2 and O_3 emissions, are included in the model. The photochemical scheme, which was specified in the lowest 17 layers corresponding to the lowest 60 km of the atmosphere, comprises the most important photochemical reactions determining the concentrations of oxygen, nitrogen, and hydrogen compounds. Continuity equations are written for the following species or groups of species: 0, O(^{1}D), O_3; N, NO, NO_2; HNO_3; H_2O_2: H, OH, HO_2 (ref. 8). For the latter group the photochemical time scales are short and dynamical processes are ignored.

The solar proton simulation experiments were performed after the model had reached a quasi steady state thus ensuring that all trace gas variations were merely due to seasonal changes. On 4 August, when the event occurred, a sudden injection of NO was introduced in the model. In a first experiment we used NO production rates for the August 1972 event as calculated by Crutzen *et al.*[3] for excited N atoms. (In fact, the differences of NO production rates between ground-state and excited N atoms only become important for altitudes above 50 km, whereas the highest ozone depletion rates through this effect are found below that altitude. Additional test runs showed that the ozone depletions for both cases differ by 7%.) A second experiment was run with the same set of NO injection rates, but multiplied by a factor of 1.7 as suggested by Arnold's findings. For both cases the solar proton-produced NO was introduced at geographical latitudes greater than 60°. It is inherent in our zonally averaged approach that geomagnetic and geographic latitudes are assumed to be coincident. The results of these experiments are given in Figs 2 and 3 for polar and mean latitudes, respectively. For comparison with the BUV data as taken from Fig. 1 (scale on *a*) the model results are plotted as relative depletions with respect to the undisturbed conditions immediately before the proton event occurred (scale on *b*). Total ozone was integrated above the 6.8 mbar level of the model which yielded the best match with the total ozone amounts indicated, obtained above 4 mbar by the BUV experiment.

For the polar latitudes (Fig. 2) the model results fit the observations reasonably well when the NO production data by Crutzen *et al.*[3] are increased by 1.7 as discussed earlier (dashed line). Without this modification, as shown by the solid line, the predicted ozone drop due to the proton event is too small. The same holds for the model results for the 55 to 65° latitude belt shown in Fig. 3. As this latitude region is covered by two adjacent latitude belts in the model, that is ~50 to 60° and ~60 to 70°, predictions of ozone depletion for both are plotted separately. Superimposing the two dashed lines, corresponding to modified NO production rates, there is, within the accuracy indicated by the error bars, good agreement with the BUV observations, before the 'recovery phase' which starts after about 20 August. If the interpretation offered by Heath *et al.* for the mid-latitude changes is correct, we should not expect a zonally averaged model to reproduce all the details of the effect. Furthermore, one should bear in mind that the ozone shows natural variations illustrated best by those observed in the tropical region (Fig. 1*a*) where the solar proton event did not cause any measurable effect.

We have investigated the changes in the ozone budget in the model following the event. Thus we have separated the net rate of change of ozone into contributions due to the photochemical and the mean and eddy transport terms. In high latitudes, the increased photochemical destruction during the event is counteracted to some extent by the transport. For instance, between about 60° and 70°N, where the perturbations to the ozone concentration are largest, the eddy terms tend to increase the ozone while the mean motion terms, which on average remove ozone from this region, are reduced in magnitude following the event.

It is interesting that the model overestimates the ozone recovery after about 23 August, at the highest latitudes considered, but underestimates it in middle latitudes. It is possible that the meteorological conditions prevailing at this particular

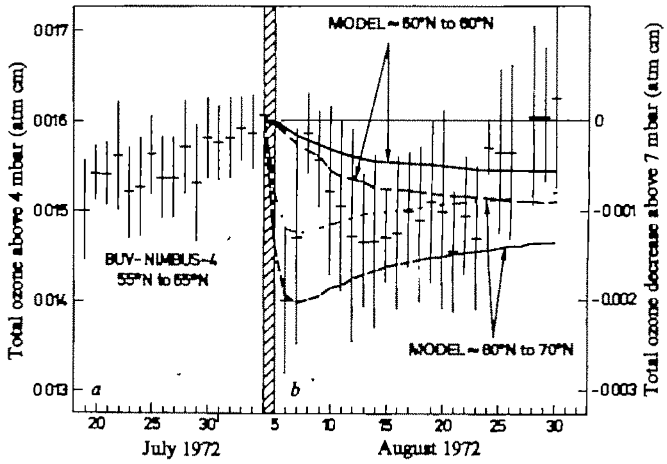

Fig. 3 Comparison of BUV–NIMBUS-4 ozone data (*a*) with model prediction for midlatitudes (*b*). The 55 to 65° N latitude range of the BUV data is somewhat between the latitude belts 50 to 60° N and 60 to 70 °N of the model. The solid line and the pointed line correspond to NO production rates given by Crutzen *et al.*[3] for the two latitude belts, respectively. The dashed lines include Arnold's modification[4].

time were such that there was a transport of ozone from high to middle latitudes, larger than calculated in the model. Clearly a model using monthly diffusion coefficients and momentum fluxes cannot be expected to reproduce dynamical changes on a synoptic time-scale. For this reason we do not discuss here our results for the Southern Hemisphere, where the calculated ozone changes were smaller, because the circulation, and thus the ozone distribution, would have been dominated by the aforementioned stratospheric warming. The model did predict temperature and circulation changes following the event but these were small, with temperature reductions not greater than 1% in the region of the greatest ozone changes. Using data from the Nimbus 4 selective chopper radiometer, the temperature sounding instrument built by the Department of Atmospheric Physics at the University of Oxford, we have looked for changes in temperature following the event. The top channel of the instrument provides information on the temperature averaged over about a 10 km thick slab in the upper stratosphere. The radiance data from this channel showed no significant changes associated with the event. It would appear that the feedback between the ozone concentration and temperature was not particularly important in this case. Indeed, our preliminary runs in which this feedback was suppressed, produced substantially the same results.

The results suggest that the NO production rates due to ionising particles are possibly higher than those originally calculated by Crutzen *et al.*[3] although the theoretical study of Porter, Jackman and Green[9] indicates even smaller rates. This work stresses the importance of the study of such natural phenomena for our understanding of atmospheric photochemistry and dynamics. It would be a major advance if, during one of the next major solar proton events, other related minor constituents could be measured. In this respect, satellite experiments such as those on Nimbus G, gain additional importance.

This work was carried out while P.F. was a visiting guest to the Department of Atmospheric Physics at Oxford. It has been, in part, sponsored by the German Federal Ministry of Research and Technology, grant No. FKW-03. The Natural Environment Research Council have supported J.A.P. and R.J.W.

Energetic protons near the plasma sheet boundary

IT has long been evident that energetic particles are produced in the Earth's magnetotail in association with magnetospheric substorms[1-6]. These particles may be important in producing ionospheric effects such as auroral zone absorption and they also lead to the injection of energetic particles into the interplanetary medium. We provide here an interpretation for the behaviour of a class of very intense, short-lived bursts of protons and other ions which appear at the edge of the plasma sheet during the expansion phase of substorms.

The characteristics of impulsive proton bursts in the magnetotail were first described by Sarris *et al.*[7] using observations of energetic proton and electron fluxes with good time resolution (~10 s) made at a geocentric distance of ~35 R_e by experiments on the spacecraft IMP 7 and 8. The bursts are observed only on the dusk side of the magnetotail, have durations of 10–30 s at a given energy (perhaps depending on the energy resolution of the detectors) and are not detected beyond ~1.8 MeV in energy. The differential proton intensities at ~300 keV can be as large as 10^5 cm^{-2} s^{-1} sr^{-1} MeV^{-1} and they are highly collimated along the magnetic field direction with anisotropies as large as 10^5:1 directed towards the tail. The most important features of the bursts is that they exhibit an inverse velocity dispersion. That is, the bursts are observed first at low energies and at higher energies some 10–20 s later, frequently when the low energy proton burst has already subsided. In general, energetic electron bursts are not observed in association with these impulsive proton bursts.

At least 12 of these bursts have been found and they have been shown by Roelof *et al.*[8] to be directly associated with the expansion phases of large geomagnetic substorms. An examination of the University of Iowa LEPEDEA spectrograms (L. A. Frank and K. L. Ackerson, personal communication) reveals that the bursts occur near the outer boundary of the plasma sheet during times when the plasma sheet disappears from the spacecraft (that is, during 'thinning'). Measurements of the magnetic field on the same spacecraft indicate that, in the case described here, the burst coincided with a transient perturbation of the magnetic field in both magnitude and direction (N. F. Ness and R. Lepping, personal communication). Observations of multiply-charged species indicate that in this event these particles behave in a similar fashion to that described above for protons (G. C. Gloeckler, personal communication).

Figure 1 shows the responses of the P1 (0.29–0.50 MeV), P2 (0.50–0.97 MeV) and P3 (0.97–1.85 MeV) channels of the

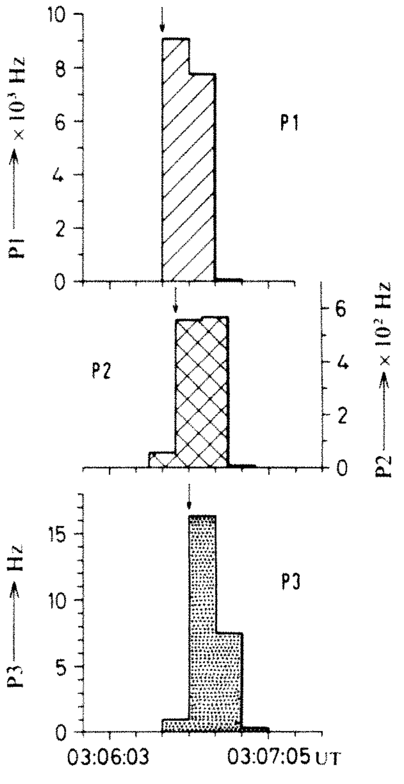

Fig. 1 Count rates of the P1 (0.29–0.50 MeV), P2 (0.50–0.97 MeV), and P3 (0.97–1.85 MeV) channels with a 10-s time resolution during the impulsive proton burst described in the text. (JHU-APL IMP 7 experiment, 27 March 1973.)

0028–0836/79/0277—0460$01.00

JHU-APL IMP 7 experiment during an impulsive proton burst which took place on 27 March 1973 at about 03.06.30 UT. The spacecraft was situated in the dusk magnetotail with solar magnetospheric coordinates $x = -31.5\ R_e$, $y = 16.6\ R_e$, $z = -5.0\ R_e$. The LEPEDEA spectrograms show that the burst was associated, to within the accuracy allowed by the observations, with a plasma sheet boundary crossing in which the plasma sheet disappeared from the position of the spacecraft. The duration of the main pulse in each energy channel was ~20 s. The University of Maryland experiment on the same spacecraft, using a detector with a smaller energy window (125–160 keV per charge, $z \geq 1$), found the pulse width to be noticeably smaller, namely ≤ 5 s (G. C. Gloeckler, personal communication). It is clear from Fig. 1 that the low energy (P1) burst was observed first and that it was followed ~10 s later by the higher energy (P3) burst. The arrows on the figure mark edges of the burst where the proton intensities increase sharply by more than an order of magnitude.

There was no electron burst associated with the proton burst, although weak fluxes of electrons were present before the burst. It is possible however, that a very short-lived ($\ll 1$ s) electron burst could have occurred and escaped detection as a consequence of the ~1.3 s spin period of the spacecraft. A telescope responding to α-particles in the energy range $0.64 \leq E \leq 1.17$ MeV per nucleus indicated that no α-particles were present in this energy range. The University of Maryland experiment detected multiply-charged ions ($z \geq 2$) with an intensity about 10% of that of all particles with $z \geq 1$ and apparently having a rather sharp energy cut-off in the range 800–1,200 keV. We have estimated the possible contribution of heavy ions to the P1, P2 and P3 counting rates using the observations of magnetospheric ion bursts reported by Fan *et al.*[9] as a basis, and find that such ions are likely to make a significant but small contribution to the counting rates. However, on the basis of the measurements presently available we cannot rule out the possibility that helium and oxygen ions (perhaps singly-ionised) make a substantial contribution to the counting rates which we have attributed to protons.

The properties of the proton bursts described above are consistent with the presence of a field-aligned sheet-like distribution of energetic protons which moves rapidly past the point of observation. The particles appear to have originated at a point on the sheet lying between the position of the spacecraft and the Earth and the magnetic field lines must be open so that the particles can escape freely. There is no evidence for any north–south difference in the occurrence of the bursts so that it can be expected that similar sheets exist simultaneously on both sides of the plasma sheet. The two sheets may therefore meet at a line where the particles originate, and this may be associated with magnetic field reconnection taking place at a neutral line which is (temporarily) situated between the spacecraft and the Earth[10]. In the following we examine the whole phenomenon from this point of view.

The situation must be such that the magnetic field lines which are reconnected at the neutral line are open, 'lobe' field lines (that is, with one end connected to interplanetary space) and with the plasma concerned being part of the very low density population observed in the lobes of the magnetotail[11]. The characteristic Alfvén speed in these circumstances is very high indeed (perhaps several thousand km s^{-1}) and one can expect that, for a short time at least, reconnection takes place very rapidly with large inductive electric fields existing in the vicinity of the neutral line and voltage drops of ~1 MV. The situation is rather similar to that found in laboratory reconnection experiments where the reconnection rate is observed to suddenly increase, with a corresponding enhanced production of energetic particles, at the time when magnetic field lines carrying low plasma densities reach the neutral point[12]. Note that these electric fields are not directly observable at ionospheric levels, however, one is naturally led to associate the neutral line with a type of auroral arc which moves rapidly polewards during the expansion phase of substorms[13–15].

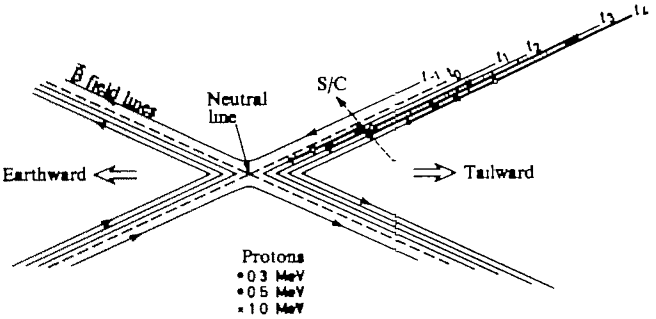

Fig. 2 Schematic diagram of the motions of magnetic field lines and the associated accelerated energetic particles resulting from magnetic reconnection. The positions of particles released from the neutral line at t_0 and at progressively later times t_1, t_2, t_3 and t_4 are shown more or less to scale, as is the motion of the spacecraft relative to the whole configuration

In this context the inverse velocity dispersion may be interpreted as follows: it is assumed that particles on a given field line are accelerated more or less simultaneously in a small region surrounding the neutral line as the field line becomes reconnected (that is at the time it reaches the neutral point). Following reconnection, the magnetic field lines carrying this population of energetic particles move tailwards and earthwards away from the neutral line and on the tailwards side, the particles stream freely away from the Earth into interplanetary space. A schematic of the motions of magnetic field lines and the energetic particles is shown in Fig. 2. Reconnection of a particular magnetic field line and the associated particle acceleration is assumed to occur at time t_0. At subsequent times (t_1, t_2, t_3, …) this magnetic field line moves away from the neutral line while the energetic particles it carries disperse along the line such that the faster particles are at any time further away from the source. During an outbound crossing of the plasma sheet boundary by a spacecraft (which is the case here, since the plasma disappears from the vicinity of the spacecraft) the magnetic field lines should appear as almost perfect 'velocity selectors' such that the lower energy particles are observed on the inner lines and the higher energy particles on the outer lines with respect to the plasma sheet. Thus particle detectors on the spacecraft could in principle detect a sequence of mono-energetic pulses with the energy increasing in time at a rate depending on the speed of the field lines and the motion of the plasma sheet boundary relative to the spacecraft. With finite energy and time resolution and a finite source size, the pulses must, of course, have finite width, but the dispersion effect will not be changed. In the present example, we estimate from the dispersion and the width of the pulses that the speed of reconnection is of the order of a few times the speed of the boundary motion, if the reconnection point is at a distance of ~20 R_e from the Earth.

How do these particles become energised? There is mounting evidence that much of the energy dissipated resistively in the reconnection process goes into the production of high energy particles[16–18]. The rather pronounced dawn–dusk asymmetry[2,7,19,20] suggests a simple cross-tail acceleration mechanism associated with magnetic field reconnection[21–23]. In this case one might expect the high energy channels to be dominated by highly charged species (for example O^{6+} and Fe^{9-13+} from the solar wind, if available) and this does not seem to be in agreement with the observations. However, if the reconnection takes place at a distance of the order of 20 R_e from the Earth it is likely that the plasma involved is of ionospheric origin and therefore singly charged. It is also possible that there could be local electrostatic acceleration in the vicinity of the neutral point, resulting from the fact that the electrons are constrained to move with the magnetic field lines, whereas the ions become 'non-magnetic' and hence the necessity for charge neutrality might require that the ions be ejected from this region. This would produce a similar energy per charge signature to the cross-tail acceleration mechanism, but the dawn–dusk asymmetry could not be easily explained. The latter seems also to be a difficulty for any stochastic mechanism as does the potentially large gyro-radii of the ions and the very high anisotropy which is produced. Finally, pulses with the reversed velocity dispersion should be observed when the plasma sheet envelopes the spacecraft during the 'thickening', which takes place at a later stage in the substorm. We expect, however, that the voltage drops prevalent at such times are much smaller than during thinning and hence that the particle bursts should be detectable only by instruments with lower energy thresholds than described here.

We thank Dr S. M. Krimigis for making available data from the Johns Hopkins University, Applied Physics Laboratory experiment on IMP-7, and Dr L. A. Frank, Dr G. C. Gloeckler, and Dr N. F. Ness for results of experiments on the same spacecraft.

Temperature dependence of atmospheric absorption in the wavelength range 8–14 μm

THE Earth's atmosphere has relatively high transparency to wavelengths between 8 and 14 μm, which makes them particularly important for communications and remote sensing. A reliable model of molecular absorption in this range is of particular value[1] as it may be used to relate atmospheric temperatures to radiant flux measurements made by artificial satellites—it seems that even in conditions when particle scattering can be neglected, absorption losses can be greater than is expected from present models. To study the remaining loss, or anomalous absorption, we have made new measurements in which particular attention was given to the temperature dependence of the anomalous component. The motivation for this was to test the hypothesis[2] that anomalous absorption could be ascribed to an equilibrium concentration of water dimers in the atmosphere. We find that this explanation cannot account for anomalous absorption in all conditions.

Measurements were made on a horizontal column of atmosphere 1.5 m above ground level and 560 m in length. The spectral observations were supplemented by laser measurements at wavelengths of 10.6 and 0.63 μm, the latter being used to quantify visibility. Standard meteorological determinations of air temperature and relative humidity were also made. A total of ~2,000 h of usable observation in various weather conditions was obtained between January and September of 1977. We have limited this discussion to conditions when the visibility was greater than 40 km so that the infrared absorption we measured would not be complicated by particle attenuation, of which the upper limit could be estimated from the visibility.

The first step in the analysis was to separate out the water monomer component which is predictable from the measured humidity and temperature. The input to these model calculations is summarised in Table 1 and a representative spectrum is shown as curve *m*–*m*′ in Fig. 1. The values of anomalous absorption were then derived by subtracting predictions from observations. Contours were formed by taking average values for each of the 15 low absorption regions (windows) shown at the top of Fig. 1 and joining up their absorption ordinates at the mid-wavelength points, the windows being chosen to exclude most of the water monomer line centres.

The attribution of anomalous absorption to water dimers rests entirely on the observed temperature dependence being in agreement with that expected from the known intermolecular binding energy of the dimer. To test the hypothesis, therefore, we used equation (1) to reduce the field observations to standard conditions of density and temperature.

$$\alpha = Cd^2 \exp(B/k\theta) \qquad (1)$$

α is an absorption coefficient in dB km^{-1}; d is the measured water vapour density; B is a temperature exponent in eV per molecule, k is Boltzmann's constant in eV per molecule per deg K; θ is the temperature in K; C is a constant containing the relevant absorption cross sections which are assumed to be independent of temperature.

The values of B were then calculated for each window wavelength and the data were also separated into low and high temperature blocks to see if the exponents were themselves dependent on temperature. The division was made at 286 K to give about equal amounts of observation in the two ranges

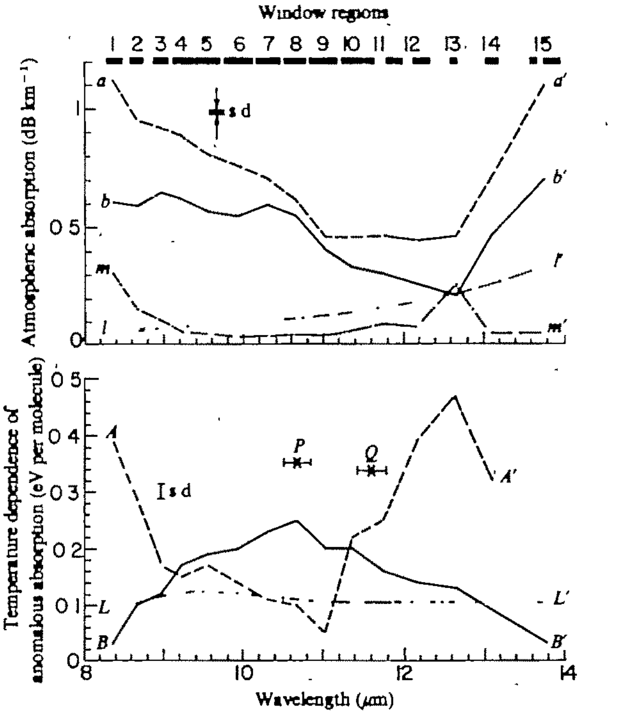

Fig. 1 Curves *a*–*a*′ and *b*–*b*′ show observed anomalous absorption values for mean temperatures of 281 and 290 K respectively, reduced to a water vapour density of 4.8 g m^{-3}. The estimated error is ±0.02 dB km^{-1}. Curves *A*–*A*′ and *B*–*B*′ are the corresponding temperature dependence values expressed as the exponent B in equation (1), with a maximum estimated error of ±0.04 eV per molecule (at 12.6 μm wavelength). Curve *l*–*l*′ shows laboratory values from ref. 3 scaled to 290 K and density 4.8 g m^{-3}, and *L*–*L*′ is the corresponding laboratory temperature dependence. Curve *m*–*m*′ shows a monomer model spectrum from the data in Table 1, for 290 K and density 4.8 g m^{-3}. The values given by *P* and *Q* are taken from ref. 1, and apply to the temperature range 258 to 299 K.

0028-0836/79/0277—0462$01 00

Table 1 Sources of data used to compute theoretical absorption spectra of monomeric water vapour and carbon dioxide in the range 8–14 μm (1,250–710 cm^{-1}) and estimates for scattering

Molecular absorption model	
Line shape	Gross[12] as formulated by Zhevakin and Naumov[13] and with corrections noted by Emery[14].
Centre frequencies Line intensities	McClatchey *et al.*[15].
Air broadened line widths	Benedict and Kaplan[16].
Criteria for inclusion in the computation	
I 601 H_2O lines in the interval 710–1,250 cm^{-1} 849 CO_2 lines in the interval 710–1,250 cm^{-1}	Lines which, at their peak, contribute 0.004 dB km^{-1} or more absorption for 4.6 torr water vapour pressure (or 330 p.p.m. CO_2) when broadened by 1 atm. of air at 273 K.
II 16 H_2O lines in the interval 500–710 cm^{-1} 377 H_2O lines in the interval 1,250–1,800 cm^{-1} 358 CO_2 lines in the interval 0–710 cm^{-1}	Lines which contribute 0.0004 dB km^{-1} or more absorption at the edges of the 710–1,250 cm^{-1} band in the above condition. In this category there are no H_2O lines above 1,773 cm^{-1} and no CO_2 lines above 1,250 cm^{-1}. No H_2O lines below 500 cm^{-1} were included.
Scattering model	When the visibility is >40 km the 0.63 μm attenuation is <0.4 dB km^{-1}. For all infrared wavelengths we have assumed a scattering component of one-tenth of the value at 0.63 μm wavelength. The average expected spectral dependence for the scattering component shows a monotonic decrease from its value at 8 μm to half the value at 14 μm wavelength.

which were specified by their mean values of 281 K and 290 K respectively.

Figure 1 shows that the measured anomalous absorption (curves *a–a′* and *b–b′*) is on average several times greater than both the monomer model absorption (curve *m–m′*) and the excess absorption which was measured in the laboratory by Burch[3] (curve *l–l′*). The spectral shapes *a–a′* and *b–b′* are also different from both the model and laboratory results. In the absence of a theoretical prediction of the strength and shape of the dimer spectrum at these wavelengths, such results by themselves give little insight to molecular models. The variation of absorption with temperature, however, is predicted by the dimer model to have a temperature exponent *B* equal to the intermolecular binding energy and this can be determined independently. Values from 0.12 to 0.16 eV per molecule are given from two different sources. One is derived from the temperature dependence of the second virial coefficient[4] and the other comes from *ab initio* calculations of the total electronic binding energy and the change in vibrational zero point energy on dimerisation[5,6]. Figure 1 shows that while the temperature exponent of absorption measured in the laboratory by Burch (curve *L–L′*) can reasonably be identified with the equilibrium dimer binding energy, the values which we measured in the real atmosphere (curves *A–A′* and *B–B′*) cannot. These are on average significantly higher, with the greatest divergence between laboratory and field results appearing at the lower mean temperature. We conclude from this that an explanation of anomalous absorption being due to water dimers for all atmospheric conditions is untenable.

In relating our results to those of other workers, Coffey[1] provides a useful survey of available data. It also includes new observations which give an even higher temperature dependence as shown by the points *P* and *Q* in Fig. 1, and it is surprising therefore that Coffey concludes that they support the equilibrium dimer hypothesis. The discrepancies between temperatures determined radiometrically from satellite observations and those made '*in situ*' also suggest that a dimer model is inadequate[7]. We note that some of the discrepancies reported are greatest at low temperatures[8] which is in line with the present results.

No alternative molecular model is yet available to explain anomalous absorption. As a pointer to possible mechanisms we note that there are other results for water vapour which show anomalously high temperature exponents at low temperatures. These are from measurements of the speed of sound[9] and of absorption[10] in the region of 7 cm^{-1}. However, as such steep temperature dependence is not predicted from equilibrium properties, we propose that the phenomena must be attributed to non-equilibrium molecular complexes of water. There is some support for this notion in the fluctuations of absorption which appeared in our measurements. These were about three times greater than could be attributed to detector noise and were too large to be caused by refractive angular scintillation. The results suggest that the dissipative absorption may itself be a time-dependent quantity whose relaxation is responsible for the fluctuations. Such variability has been reported elsewhere[11].

Our results show that new molecular phenomena may have to be considered in the search for a better understanding of 10-μm region absorption and the importance of satellite radiometry alone points to the pressing need for this. If, as we suggest, non-equilibrium phenomena do play a part, this will complicate modelling but may bring some benefit, as it suggests that a systematic study of absorption fluctuations could lead to an improved understanding of the underlying physics.

The measurements were made at the Royal Aircraft Establishment, Farnborough and we thank R. R. Allan, S. Craig, T. D. F. Hawkins and P. Ashdown for their cooperation. This work was supported by the Procurement Executive, Ministry of Defence.

Effects on prolific petroleum source rocks and major coal deposits caused by sea-level changes

THE nature and abundance of planktonic organic matter—the main source of crude oil—and moreover its preservation in sediments are affected by sea-level changes. Deposition of paralic coals might be also influenced. It is shown here that these

0028-0836/79/0277—0463$01 00

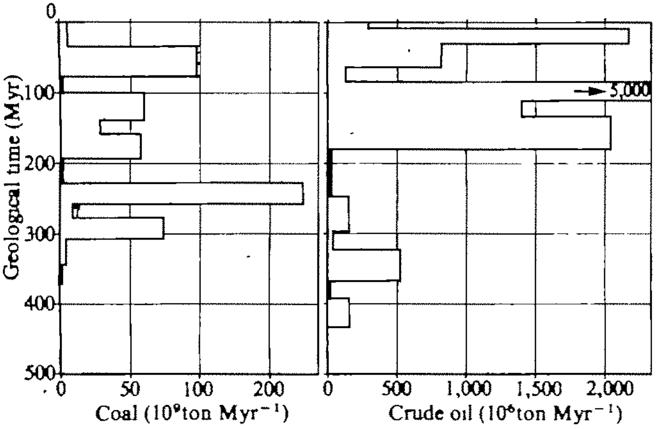

Fig. 1 Distribution of coal and petroleum as a function of geological time. The surface of the block areas is proportional to the total resources (in place, not necessarily recoverable) in geological series of each period. Data on coals, from Strakhov[1], are related to world reserves. Data on crude oil, from Bois *et al.*[2] are related to 148 petroleum zones, amounting to ~85% of the world resources. The age plotted for crude oil is the age of the source rock.

considerations would explain large accumulations of coal or petroleum source rocks over relatively short periods of time.

Available evidence indicates that coal and petroleum are unevenly distributed among geological periods. Figure 1 shows the time distribution of coal (world reserves[1]) and petroleum source rocks. The latter is plotted in terms of total—not necessarily recoverable—oil stored in reservoirs derived from the source rock. The plot includes 148 petroleum zones (ref. 2 and C. Bois, personal communication) of the world amounting to ~400×10^9 tons of oil in reservoirs. Prolific petroleum source rocks, deposited over part of Jurassic and Cretaceous (from 180 to 85 Myr) are responsible for 70% of the crude oil in these 148 petroleum zones; however, this interval amounts to 17% only of the time elapsed since the Precambrian. Considerable accumulations of coal occurred during Middle and late Carboniferous, Middle and Upper Permian, Lower and Middle Jurassic, Lower Cretaceous, and uppermost Cretaceous to Eocene. These intervals amount to 30% only of the time elapsed since the Precambrian, but they integrate ~95% of the world reserves of coal.

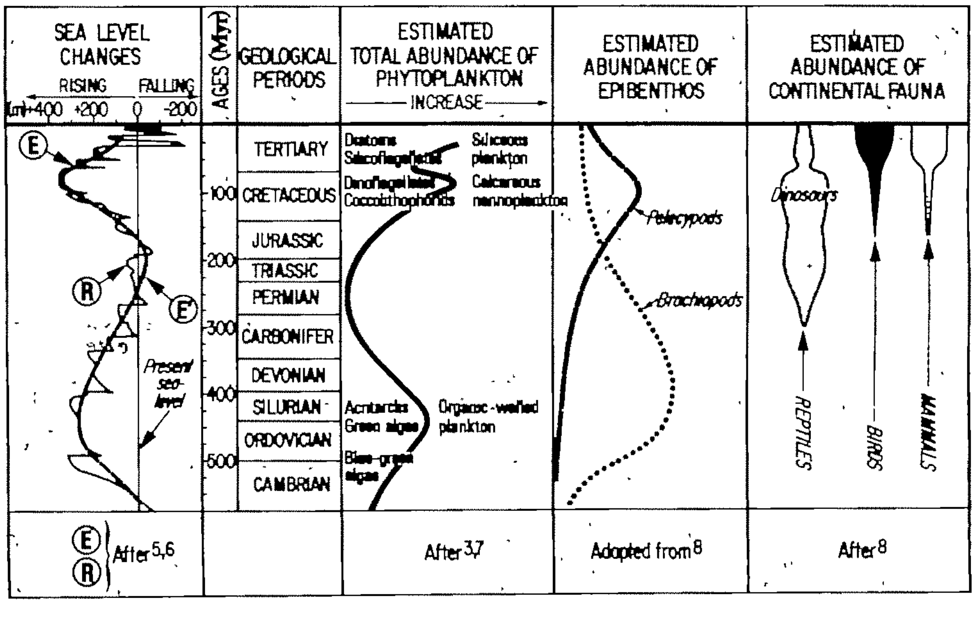
Organic geochemical studies have shown that source rocks able to generate large quantities of oil have specific characteristics. They contain an abundant organic matter of planktonic and/or bacterial origin, preserved and deposited in a reducing environment[3]. The resulting kerogen belongs to types I or II defined by Tissot *et al.*[4] on the basis of elemental analysis and infrared (IR) spectroscopy. However, the cause for accumulating large quantities of this material over wide areas during certain periods of time was not clear.

Recent developments in marine geology and geophysics made possible a comparison of these events with global sea-level changes. Pitman[5] showed that absolute rise or fall of sea-level are caused by the volume changes of the mid-oceanic ridge system. These changes are mainly due to change in spreading rate and to creation or destruction of a ridge system. The sea level (curve E, Fig. 2) was ~+350 m above present in the late Cretaceous (85 Myr) and fell to +60 m in Middle Miocene (15 Myr). Since that time glacial fluctuations may have dominated sea-level changes. Vail[6] studied the relative changes of sea level, that is, its rise or fall with respect to land surface, from the onlap of coastal deposits in seismic records of maritime sequences (curve R, Fig. 2). Both curves E and R show a good agreement, with respect to general trend and average value. Thus, it is possible to extend curve E from Cretaceous to Palaeozoic by E′ (averaging the general trend of R): two major cycles[6] of sea-level rise and fall occurred from Cambrian to Triassic (570–200 Myr) and from Jurassic to present (200–0 Myr).

Productivity and composition of marine phytoplankton—the main primary producer of marine organic matter—seems greatly influenced by these global cycles. An estimation of its total abundance shows two distinct maxima (Fig. 2) corresponding to the highest sea level, the largest extension of epicontinental seas, which are more productive than deep oceans[3]. Furthermore, the first cycle was governed by organic-walled plankton (acritarchs, green and blue-green algae), whereas the second cycle was dominated by calcareous nannoplankton (coccolithophorids, dinoflagellates) and later siliceous plankton (silicoflagellates, diatoms[3]). Dominant epibenthic faunas[8] were also replaced. On land, the disappearance of lowland plains in late Cretaceous time (sea level 350 m above present) may also be responsible for some dramatic changes of fauna.

Preservation of organic matter is a crucial point for deposition of rich source rocks. The main factors of destruction of this material are feeding heterotrophic animals and biochemical degradation by aerobic bacteria: thus the absence of oxygen in waters and in freshly deposited sediments is the main condition for preservation[9]. Shallow epicontinental seas transgressive over continental depressions often fulfill this requirement. The sea is surrounded by emergent lands, providing mineral nutrients and favouring algal blooms. In turn, the blooms resulted in an abundant bacterial consumption of oxygen and provided temporary anoxic conditions in the landlocked sea, where waters were not sufficiently renewed[10]. In deeper waters, anoxic

Fig. 2 Global cycles of absolute (E) and relative (R) sea-level changes, according to Pitman[5] and Vail[6], and their influence on marine and terrestrial populations. Estimated abundance of phytoplankton[7] shows two maxima corresponding to the highest sea-level positions. Its dominant composition[3] changes from one cycle to the other, and also that of epibenthos[8]. Terrestrial faunas[8] are also drastically changed after the highest sea-level of late Cretaceous.



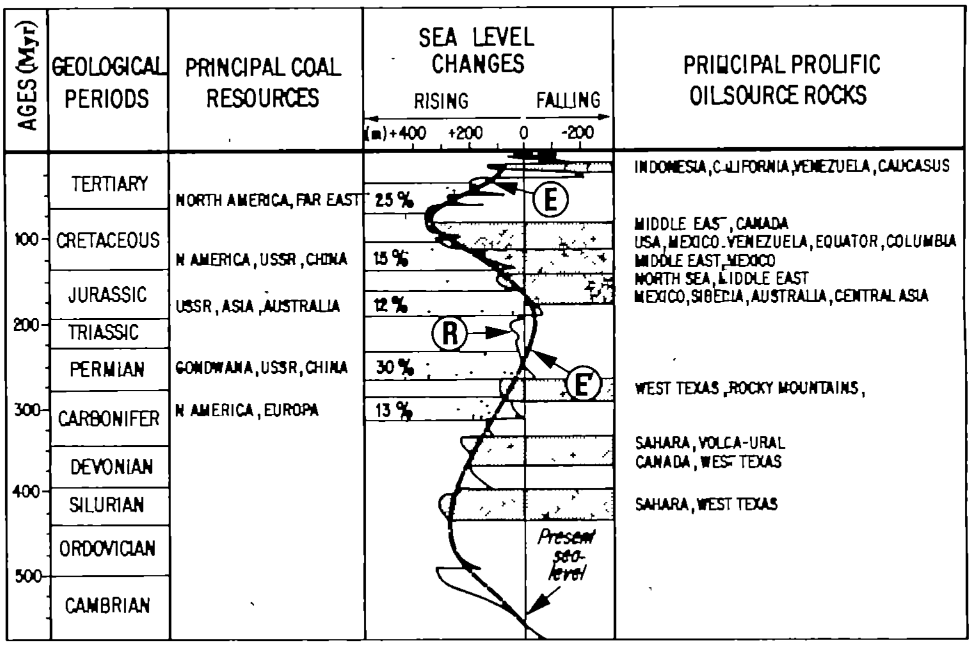


Fig. 3 Principal periods of deposition of prolific oil source rocks and major coal deposits are compared with worldwide transgressions and regressions. The periods considered for petroleum source rocks are responsible for more than 10^8 tons of oil Myr^{-1} during the first cycle (570–200 Myr) and more than 10^9 tons Myr^{-1} during the second cycle (200–0 Myr).

basins, such as the Black Sea, or areas associated with upwelling may provide comparable conditions.

Worldwide transgressions over the continental platform have been observed. Transgressions and regressions result from the balance of the rate of sea level rise or fall and the rate of subsidence minus sedimentation rate. Thus worldwide transgressions may be caused by changes of the rate of sea level rise or fall[5]. The second-order cycles of curve R (Fig. 2) illustrate these events[6]: a transgression appears as a rise of R with a positive departure compared to E–E′; a regression appears as a fall of R with a negative departure. The comparison of these cycles with the major occurrences of prolific oil source rocks (Fig. 3) indicates that they were mainly deposited during periods of global marine transgressions. For instance, the Silurian transgression deposited the rich source rocks of the Sahara over the glacial topography inherited from the Ordovician continent. In Western Europe, the successive Jurassic transgressions over the Triassic continent deposited the source rocks of the North Sea and the Toarcian and Kimmeridgian oil shales (France, Germany, UK).

However, the potential for oil generation seems to be lower by about 1 : 10 in the older cycle, as compared to the younger one. This is probably due to a greater thermal maturation—generating gas—and to tectonic events (faults, folding and erosion) which have destroyed a large part of the oil originally formed.

Most important coal occurrences were formed by large accumulations of terrestrial higher plants in coastal or paralic basins. A long-lasting subsidence is necessary to provide thick series of shallow deposits and a moderate relief of the hinterland to avoid dilution by inorganic material. The most typical environment is provided by coastal lowlands with swamps which develop after regression of the sea. The comparison of the age of the major coal deposits—$> 50 \times 10^9$ tons Myr^{-1}—with the second-order cycles of curve R (Fig. 3) indicates a frequent correlation with worldwide regressive periods.

Trace elements in the fluid phase of the Earth's mantle

It has become apparent during the past decade or so that CO_2 is a significant component of the Earth's upper mantle. In addition to the indirect evidence including CO_2 emanations from volcanoes throughout the world and the abundance of CO_2 in kimberlites and carbonatites, it is now known that CO_2 is ubiquitously present in xenoliths of mantle material brought up in alkalic basalts and kimberlites. This latter point was first made by Roedder[1] who demonstrated that the fluid in optically visible inclusions is essentially pure CO_2 under pressures as great as 5 kbar at eruptive temperatures. Such pressures provide only a minimum depth of origin, because Roedder further showed that most of the inclusions he observed are secondary, that is, they occur as arrays on healed cracks. A more recent study[2] indicated pressures as high as 10 kbar in secondary inclusions. H.W.G. and Radcliffe[3] found, using transmission electron microscopy (TEM), that submicroscopic fluid inclusions also occur within the crystals of mantle xenoliths, and that these bubbles have exsolved (precipitated) from solid solution. Thus, at least the CO_2 now present in submicroscopic fluid inclusions is indigenous to the crystals in which it is found, and probably represents the source of crack formation and filling to produce the secondary inclusions on the way to the surface[3]. The effect CO_2-bearing phases have on the distribution of trace elements in the mantle and during partial melting is considered here.

The term 'fluid inclusion' is used here as a descriptive term only; I reject the usual connotation that the fluid has been 'included' into the crystals as a growth accident in an igneous environment. For example, virtually all of the rocks in question are metamorphic and show no signs of introduction of a fluid phase from an external source. Moreover, metamorphic recrystallisation 'excludes' fluid and concentrates it onto grain boundaries, rather that 'including' it during grain growth[3].

CO_2 would appear, then, to be an important component of most, perhaps all, of the upper mantle and two questions are paramount: (1) in what phases does the CO_2 reside in the upper mantle?; and (2) what effect do these CO_2-bearing phases have on the partitioning of trace elements within the mantle and between melt and residuum during partial melting? The former is easier to answer. There now seems to be too much CO_2 (at

0028-0836/79/0277—0465$01 00

least in the uppermost mantle) for it simply to be dissolved in the silicates as originally assumed by H.W.G.[4]; moreover, recent experimental work indicates that in the mantle beneath undisturbed continents, the CO_2-bearing phase is probably a carbonate[5-7] and beneath oceans the stable phase may be a carbonate[5,6] or supercritical fluid[7]. All the data strongly suggest, however, that because of the steeper geothermal gradient in the vicinity of an oceanic ridge, the stable phase in the lithosphere under ridges will be fluid CO_2. The second question is more difficult to answer, but is fundamentally more important because the concentrations of trace elements in melts derived from the mantle are routinely used to infer the present composition of the upper mantle and its geochemical evolution. These inferences are always based on calculated or experimentally determined element partitioning between basaltic melt and mantle silicates, especially clinopyroxene and garnet. If significant quantities of these elements reside in another phase—a CO_2-bearing phase—and if portions of this phase are not incorporated into the melt, then current interpretations of trace element data could be in error. The ubiquitous occurrence of CO_2 inclusions in refractory xenoliths such as harzburgite and dunite indicates that melt extraction does not scavenge all of the CO_2-bearing phase.

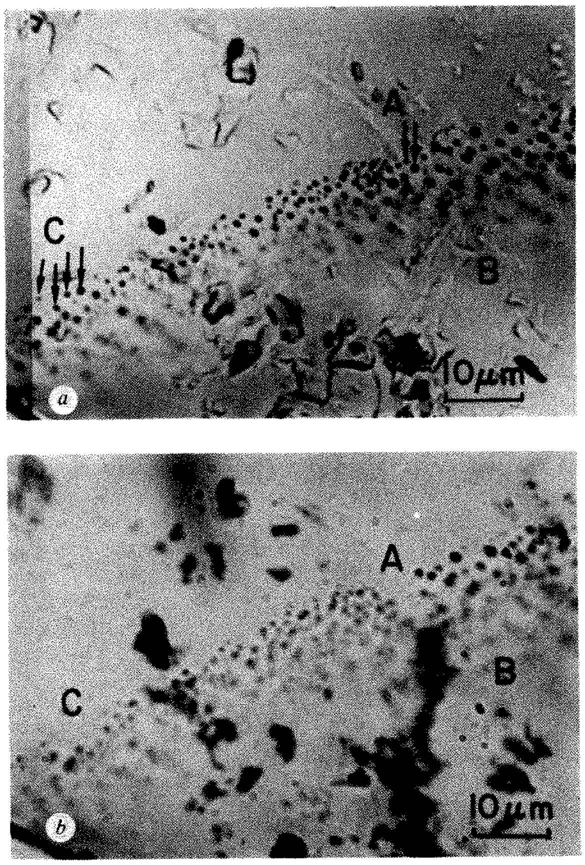

Fig. 1 Photomicrographs showing region of olivine specimen H-1 before (*a*) and after (*b*) ion probing. A healed crack decorated with 2-phase CO_2 bubbles intersects the top of the thin section along line AC. Arrows in (*a*) point to bubbles which were removed by sputtering and are absent in (*b*). Irregular black and grey areas in (*b*) are surface pits from which the gold film could not be removed after probing.

As a first step to determination of the trace element problem, an ion probe study has been inaugurated to attempt detection of trace elements in CO_2 inclusions[8]. The procedure chosen was to 'drill' down through host crystal and break bubbles. To simplify the initial search, elements known to be major components of carbonatites and to have no good crystallographic home in mantle phases (olivine, orthopyroxene, clinopyroxene, garnet, spinel) were chosen as good candidates. In addition, mass numbers known to give interfering peaks produced by the matrix elements and polyatomic reaction products of matrix elements with the ^{16}O beam were omitted. For example, ^{12}C, ^{28}CO, $^{44}CO_2$, ^{40}Ca, ^{40}Ar were not attempted due to interference with $^{24}Mg^{2+}$, ^{28}Si, ^{44}SiO and ^{40}MgO respectively. Five or six different mass numbers were searched in each run, including trace elements and elements to serve as internal monitors of the matrix, such as ^{24}Mg. The results were positive for masses 39(K) and 47(Ti), suggestive for mass 140(Ce) and inconclusive for masses 1(H), 85(Rb), 86(Sr), 87(Sr), 138(Ba), 142(Ce) and 208(Pb).

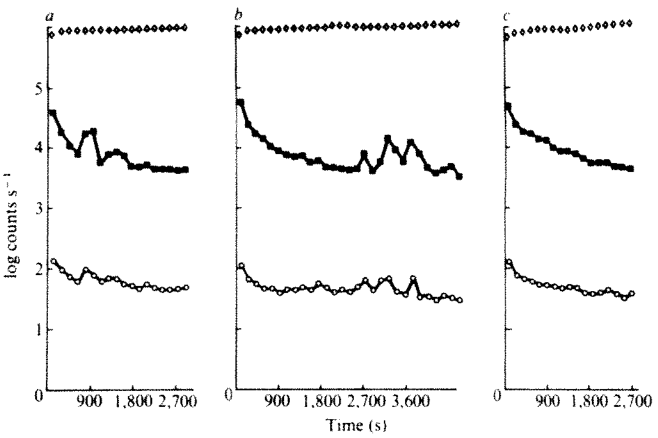

Fig. 2 Depth profiles for masses 24, 39 and 47 obtained from areas A, (*a*) C, (*b*) and B (*c*) of Fig. 1. Area B is a control profile obtained where no (optically visible) bubbles were present. ■, ^{39}K; ○, ^{47}Ti; ◇, ^{24}Mg.

A portion of a bubble array on a healed crack in olivine of dunite specimen no. H-1 from the 1801 Kaupulehu lava flow of Hualalai volcano, Hawaii, is shown in Fig. 1*a* before ion probing and in Fig. 1*b* after probing. At site C, four inclusions were removed during bombardment of the surface for 80 min with a 15 nA ^{16}O beam of elliptical cross-section (~8 µm × 15 µm). Mass numbers were examined sequentially with each mass counted for 5 s, except for ^{24}Mg which was counted for 3 s. The concentration profile produced during the erosion at site C is given in Fig. 2*b*. The four distinct peaks in masses 39 and 47 are presumed to correlate with the four bubbles removed by sputtering; no corresponding peaks (or valleys) in ^{24}Mg are observed.

Another profile measured at site A of the same inclusion array broke two bubbles (Fig. 1) and shows two peaks (Fig. 2*a*), whereas a control profile measured at site B in the same olivine crystal in an area of no fluid inclusions shows no peaks (Fig. 2*c*). Figure 3 shows similar results for an olivine crystal of lherzolite specimen No. SAL-3 from Salt Lake Crater, Oahu, Hawaii, and Fig. 4 shows the results of a long profile of an orthopyroxene crystal of this same specimen. The apparent noise in the mass 39 data of the latter profile is produced by breaking numerous small inclusions (≤ 1 µm diameter) and three larger ones (~5 µm diameter). Of particular interest in the mass 39 profile of Fig. 4 is the large, double peak between 6,200 and 7,400 s, and the secondary one between 7,800 and 8,500 s. These probably represent penetration of the three larger bubbles. These peaks correspond exactly to the highest values of the mass 140 profile which also shows a large, divided peak and a narrower one. Although the maximum count-rate is 4.5 c s⁻¹ for mass 140, this represents 2.9 standard deviations above the mean of all data points after surface contamination had been removed (2,700 s). Similarly, the two subsidiary peaks represent 1.8 standard deviations above the mean. Thus, the data can reasonably be considered significant on their own, and correspondence with the largest peaks in mass 39 increases the likelihood that these inclusions contain detectable amounts of cerium.

Quantitative interpretation of these data depend on the ionisation and collection efficiency of the ions involved, which, in turn, critically depend on whether the elements in question are in the fluid itself or are present as a solid film on the surface of the bubbles. For potassium, for instance, the fraction of atoms detected from a fluid is of the order of 10^{-3}, but from a solid substrate is ~0.6 (T. Whatley, personal communication). Two lines of evidence strongly suggest that the trace elements detected here are in a surface film: (1) If the efficiency of detection is 10^{-3}, the K content of the bubbles in Fig. 2 is >10%, an apparently unreasonably high value. On the other hand, if the detection efficiency is 0.6, the K content is about 1,000 p.p.m. of the fluid contents; (2) the peaks last too long. The best example of this phenomenon is the double peak in Fig. 4, which lasts for 20 min. During this time the beam will have eroded about 0.5 μm deeper into the pyroxene crystal and opened an orifice as large as 3 μm across on the 5 μm bubble(s). We can expect that the fluid, under very high pressure, would escape in the first few seconds of this time, hence the mass 39 and 140 elements cannot be in the fluid phase itself. It would seem most reasonable to conclude, therefore, that the trace elements detected in this study were originally in the fluid at high pressure and high temperature, but are now located in a film on the bubble walls; after penetration of the bubble, the ion beam 'washes out' the thin film.

Masses 39 and 47 which have been definitely detected here, are not uniquely interpreted as K and Ti; they could be ^{39}NaO and ^{47}PO. Na is unlikely to be a major contributor to the peaks reported here because the vast majority of Na is always registered at mass 23. A significant contribution of Na at mass 39 would therefore imply a very large Na content to the inclusions, a composition inconsistent with the conventional fluid inclusion studies[1,2]. ^{31}P, however, is commonly detected as ^{47}PO with an ^{16}O beam (T. Whatley, personal communication) and hence may be a significant, even dominant contributor to the peaks at mass 47. In this regard it is important to distinguish the results of this study and the analysis of glassy rims sometimes found on fluid inclusions in these rocks. Although K, Na, Ti and P have been detected in such rims[2], the surface film detected here seems to be a different phenomenon. Most inclusion arrays in peridotite xenoliths contain only fluid. This has been determined by optical observation of the brownian motion of the inner vapour bubble when the inclusions are sufficiently large (≫2 μm diameter), and by TEM when they are not. In every array investigated, when all of the large inclusions show an inner bubble in motion and no glass rim, the TEM confirms the absence of a glass rim on the smaller inclusions. Some submicroscopic inclusions, however, do suggest a very thin (<100 Å) surface film, which I have so far been unable to convince myself was definitely present. Furthermore, the three larger inclusions originally present in specimen SAL 3-14 (Fig. 4) displayed moving vapour bubbles and lacked a glassy rim. The volume fraction of fluid is thus very much larger in the inclusions described here than in those with glassy rims figured by Roedder[1] and Murck *et al.*[2], and it would seem difficult to interpret my results as evidence of an immiscible silicate liquid incorporated along with the CO_2. It seems more likely that these elements were dissolved in the fluid at high pressure.

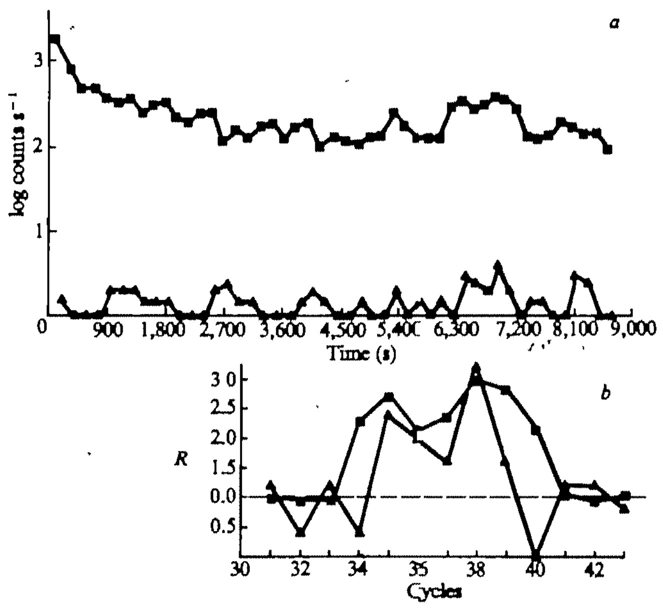

Fig. 4 Depth profile for masses 39 and 140 for area 14 of specimen SAL-3. Large doublet, peak between 6,200 and 7,400 s (cycles 33–43) is replotted in (*b*) in terms of the ratio (*R*) of counts s^{-1} divided by the average counts s^{-1} for cycles 33–43. ■, ^{39}K; ▲, ^{140}Ce

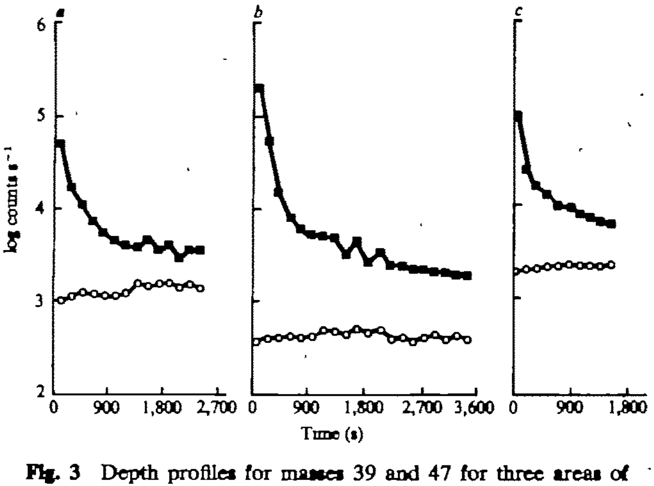

Fig. 3 Depth profiles for masses 39 and 47 for three areas of specimen SAL-3: *a*, SAL-3-14A; *b*, SAL-3-26A; *c*, SAL-3-25A. Profile 25A is a control obtained where no (optically visible) bubbles were present. ■, ^{39}K; ○, ^{47}Ti.

The results of this study demonstrate that the CO_2-bearing phase in the mantle contains significant quantities of cations other than carbon. They do not, however, help much in determination of whether the CO_2 was already a fluid or was in a carbonate when it began its trip to the surface (because the inclusions analysed are secondary and could conceivably represent the product of carbonate breakdown). However, other workers have shown that the CO_2 bubbles in xenoliths also contain significant quantities of noble gases[9–11]. Of major interest is the detection of excess ^{129}Xe (ref. 11) with its implication that the Earth formed within 76 Myr of nucleosynthesis[12] and has not been totally outgassed since that time[11,12]. Another point of major importance is the large quantity of ^{40}Ar, giving anomalously old K/Ar ages. These latter observations suggest that the CO_2-bearing phase has acted as a sink for rare gases—a property which is more likely to characterise a fluid than a carbonate.

Finally, the detection of alkalis and a suggestion of light rare earths suggest caution in interpretation of mantle compositions from basalt chemistry using silicate-liquid partition coefficients.

Speciation of dissolved iodine in estuarine waters

IODINE in seawater is present as iodate (IO$_3^-$) and as iodide (I$^-$)[1-3]. Although there is some uncertainty in the true redox potentials of natural waters[4], the thermodynamically stable species of iodine in seawater, and in river waters which are well oxygenated, is iodate[5-7]. We have studied an estuary to determine the distribution of iodine species as a function of salinity, and examined the results for evidence of interconversion of species in the estuary. We report here that iodide is the dominant form in river water and is oxidised to the thermodynamically stable iodate in the sea, not in the estuary.
